Algorithmic Thinking

FIT 100

To be effective computer users it is necessary to have a general idea how to make a computer solve a problem. Thinking algorithmically is a necessary first step towards solving a problem by computer.

An Assistant's Assistance

❖ An algorithm is a systematic method for deterministically producing a specified result

❖ Two participants --
  ❑ The person specifying the algorithm is a *programmer*
  ❑ Some other agent (person or computer) will *execute* the algorithm, i.e. follow its instructions, without intervention of the programmer

❖ Recipes are an example of algorithms written by chefs and followed by cooks to produce a specified food

> S'mores: Place a toasted marshmallow on a Graham cracker and then place a square of chocolate on top

The 5 Properties of Algorithms

❖ All algorithms must have certain properties if the agent is to execute them successfully without intervention by the programmer

- ❏ Input specified
- ❏ Output specified
- ❏ Definiteness
- ❏ Effectiveness
- ❏ Finiteness

Input/Output Specified

- ❖ The "input" is the data that will be transformed by the algorithm to create the output

- ❖ In giving an algorithm, state
  - ❏ The type of data expected -- whole numbers, letter strings
  - ❏ The number of data items expected
  - ❏ The structure, if any, of the data expected -- a list, table, etc.

- ❖ The "output" is the result of the computation -- its description often forms the name of the algorithm

- ❖ The features specified are the same as for input
  - ❏ The types of data forming the result
  - ❏ The number of data items forming the result
  - ❏ The structure of the result

Definiteness

- ❖ An algorithm must be explicit about how to realize the computation

- ❖ Definiteness is achieved by giving commands that state unambiguously what to do, in sequence

- ❖ The commands may be …

  - ❑ Conditional, i.e. require a decision to be made, and so must be explicit about how to respond to all different outcomes

  - ❑ Repeated, and so must be explicit about when to stop the repetition

The definiteness property assures that the executing agent will always know what command to perform next

Effectiveness

- ❖ Effectiveness assures that the agent can perform the algorithm's operations mechanically without intervention
    - ✛ No additional inputs, special talent, clairvoyance, creativity or help from Superman
- ❖ Effectiveness is achieved by reducing the task to the primitive operations known to the computer
- ❖ Definiteness assures the agent knows what command to perform next; effectiveness assures the agent can accomplish the command

A non-effective command would be "Print the NASDAQ's net change for the next trading day"

Finiteness

- ❖ An algorithm must eventually terminate with either
  - ✦ The right output
  - ✦ An indication that no solution is possible

- ❖ A non-terminating algorithm is useless since it is impossible to distinguish between continued progress and being "stuck"

- ❖ Finiteness is relevant to computer algorithms since they typically repeat instructions

```
         3.3
       ‾‾‾‾‾‾‾‾‾‾‾‾‾‾
    3)10.0000000000...
        9
       ‾‾‾
       10
         9
        ‾‾‾
         1
```

Language

- ❖ People write algorithms, but some other agent will execute them … so they must be expressed in some language

- ❖ English and other natural languages are poor choices

  - ✦ Ambiguous -- multiple interpretations of an utterance

    "Her lasagna is not very hot"

  - ✦ Imprecise -- exact meanings have not been assigned to all words and sentences: *all deliberate speed*

  - ✦ Recipes try: *stir* is not a synonym for *fold* or *beat*

- ❖ Programming languages are formal notations specifically designed for specifying algorithms

- ❖ Visual Basic is the language we'll use

Alphabetize CDs
- ❖ *Input*:   Unordered CDs filling a slotted rack
- ❖ *Output*: CDs in slotted rack, alphabetized

Alphabetizing Algorithms

1 "*Artist_Of*" means the name of the group

2 Pick one end of the rack to be the beginning of the alphabetic sequence. Call that end's slot the "*Alpha*" slot

3 Call the slot adjacent to the *Alpha* slot the "*Bet*" slot

4 If the *Artist_Of* the CD in the *Alpha* slot is later in the alphabet than the *Artist_Of* the CD in the *Bet* slot, then interchange the CDs

5 If there is a slot following the *Bet* slot, begin calling it the "*Bet*" slot and go to step 4; otherwise, continue on

6 If there are two or more slots following the *Alpha* slot, then begin calling the slot following the *Alpha* slot, "*Alpha*" and the slot following it the "*Bet*" slot, and go to step 4; otherwise, stop

Algorithm vs Program

- ❖ A program is simply an algorithm specialized to a particular situation …
- ❖ Alphabetize CDs is an instance of Exchange Sort
- ❖ Exchange Sort can be specialized to other cases
  - ✦ Sort CDs by other criteria, e.g. title
  - ✦ Sort books by title or other criteria
  - ✦ Sort canceled checks, students' homework assignments, vehicles, etc.

The algorithm, being a process with only a limited number of specifics given, is more abstract than is the program
