# Scaling the mirror

- Let's modify our Mirror program so that it can scale.
  - The current mirror (left) is at size 4; the right is at size 3.
- We'd like to structure the code so we can scale the figure by changing the code in just one place.

```
#=====#
|      <><>      |
|      <>....<>      |
|  <>.....<>  |
|<>.....<>  |
|<>.....<>  |
|  <>.....<>  |
|      <>....<>      |
|      <><>      |
#=====#
```

```
#=====#
|      <><>      |
|      <>....<>      |
|  <>.....<>  |
|<>.....<>  |
|<>.....<>  |
|  <>....<>  |
|      <><>      |
#=====#
```

# Limitations of variables

- Idea: Make a variable to represent the size.
  - Use the variable's value in the methods.
- Problem: A variable in one method can't be seen in others.

```
public static void main(String[] args) {  
    int size = 4;  
    topHalf();  
    printBottom();  
}  
  
public static void topHalf() {  
    for (int i = 1; i <= size; i++) {      // ERROR: size not found  
        ...  
    }  
}  
  
public static void bottomHalf() {  
    for (int i = size; i >= 1; i--) {      // ERROR: size not found  
        ...  
    }  
}
```

# Variable scope

- **scope:** The part of a program where a variable exists.
  - From its declaration to the end of the { } braces
    - A variable declared in a `for` loop exists only in that loop.
    - A variable declared in a method exists only in that method.

```
public static void example() {  
    int x = 3;  
    for (int i = 1; i <= 10; i++) {  
        System.out.println(x);  
    } // i no longer exists here  
} // x ceases to exist here
```

i's scope

x's scope

# Scope implications

- Variables without overlapping scope can have same name.

```
for (int i = 1; i <= 100; i++) {  
    System.out.print("//");  
}  
for (int i = 1; i <= 100; i++) { // OK  
    System.out.print("\\\\");  
}  
int i = 5; // OK: outside of loop's scope
```

- A variable can't be declared twice or used out of its scope.

```
for (int i = 1; i <= 100 * line; i++) {  
    int i = 2; // ERROR: overlapping scope  
    System.out.print("//");  
}  
i = 4; // ERROR: outside scope
```

# Class constants

- **class constant:** A value visible to the whole class.
  - value can only be set at declaration
  - value can't be changed while the program is running
- Syntax:

```
public static final type name = value;
```

- name is usually in ALL\_UPPER\_CASE
- Examples:

```
public static final int DAYS_IN_WEEK = 7;  
public static final double INTEREST_RATE = 3.5;  
public static final int SSN = 658234569;
```

# Constants and figures

- Consider the task of drawing the following scalable figure:

# Multiples of 5 occur many times

+/\ \ / \ / \ / \ / +  
| |  
| |  
+/\ \ / \ / \ / \ / +

The same figure at size 2

# Repetitive figure code

```
public class Sign {  
  
    public static void main(String[] args) {  
        drawLine();  
        drawBody();  
        drawLine();  
    }  
  
    public static void drawLine() {  
        System.out.print("+");  
        for (int i = 1; i <= 10; i++) {  
            System.out.print("/\\\"");  
        }  
        System.out.println("+");  
    }  
  
    public static void drawBody() {  
        for (int line = 1; line <= 5; line++) {  
            System.out.print("|");  
            for (int spaces = 1; spaces <= 20; spaces++) {  
                System.out.print(" ");  
            }  
            System.out.println("|");  
        }  
    }  
}
```

# Adding a constant

```
public class Sign {  
    public static final int HEIGHT = 5;  
  
    public static void main(String[] args) {  
        drawLine();  
        drawBody();  
        drawLine();  
    }  
  
    public static void drawLine() {  
        System.out.print("+");  
        for (int i = 1; i <= HEIGHT * 2; i++) {  
            System.out.print("/\\\"");  
        }  
        System.out.println("+");  
    }  
  
    public static void drawBody() {  
        for (int line = 1; line <= HEIGHT; line++) {  
            System.out.print("|");  
            for (int spaces = 1; spaces <= HEIGHT * 4; spaces++) {  
                System.out.print(" ");  
            }  
            System.out.println("|");  
        }  
    }  
}
```

# Complex figure w/ constant

- Modify the Mirror code to be resizable using a constant.

A mirror of size 4:

```
#=====#
|      <><>      |
|      <>....<>      |
|  <>.....<>      |
|<>.....<>      |
|<>.....<>      |
|  <>.....<>      |
|      <>....<>      |
|          <><>      |
#=====#
```

A mirror of size 3:

```
#=====
|      <><>      |
|      <>....<>      |
|<>.....<>      |
|<>.....<>      |
|  <>....<>      |
|      <><>      |
#=====#
```

# Using a constant

- Constant allows many methods to refer to same value:

```
public static final int SIZE = 4;

public static void main(String[] args) {
    topHalf();
    printBottom();
}

public static void topHalf() {
    for (int i = 1; i <= SIZE; i++) {      // OK
        ...
    }
}

public static void bottomHalf() {
    for (int i = SIZE; i >= 1; i--) {      // OK
        ...
    }
}
```

# Loop tables and constant

- Let's modify our loop table to use SIZE

SIZE	line	spaces	$-2*line + (2*SIZE)$	dots	$4*line - 4$
4	1,2,3,4	6,4,2,0	$-2*line + 8$	0,4,8,12	$4*line - 4$
3	1,2,3	4,2,0	$-2*line + 6$	0,4,8	$4*line - 4$

```
#=====#
|      <><>      |
|      <>....<>    |
|      <>.....<>   |
|<>.....<>       |
|<>.....<>       |
|      <>.....<>   |
|      <>....<>    |
|      <><>      |
#=====#
```

```
#=====#
|      <><>      |
|      <>....<>    |
|      <>.....<>   |
|<>.....<>       |
|<>.....<>       |
|      <>....<>   |
|      <><>      |
#=====#
```

# Partial solution

```
public static final int SIZE = 4;  
// Prints the expanding pattern of <> for the top half of the figure.  
public static void topHalf() {  
    for (int line = 1; line <= SIZE; line++) {  
        System.out.print("|");  
  
        for (int space = 1; space <= (line * -2 + (2*SIZE)); space++) {  
            System.out.print(" ");  
        }  
  
        System.out.print("<>");  
  
        for (int dot = 1; dot <= (line * 4 - 4); dot++) {  
            System.out.print(".");  
        }  
  
        System.out.print("<>");  
  
        for (int space = 1; space <= (line * -2 + (2*SIZE)); space++) {  
            System.out.print(" ");  
        }  
  
        System.out.println("|");  
    }  
}
```

# Observations about constant

- It doesn't replace *every* occurrence of the original value.
  - "Different fours" for different reasons
  - A good reason to use variables to keep things straight

```
for (int dot = 1; dot <= (line * 4 - 4); dot++) {  
    System.out.print(".");
}
```

- Even if you're not interested in scaling, constants can make algorithms clearer
  - Avoids "magic numbers"

# Building Java Programs

## Chapter 3 Lecture 3-1: Parameters

**reading: 3.1**

exercises: #1-3

videos: Ch. 3 #1, 4

# Redundant recipes

- Recipe for baking **20** cookies:
  - Mix the following ingredients in a bowl:
    - **4** cups flour
    - **1** cup butter
    - **1** cup sugar
    - **2** eggs
    - **1** bag chocolate chips ...
  - Place on sheet and bake for about **10** minutes.
- Recipe for baking **40** cookies:
  - Mix the following ingredients in a bowl:
    - **8** cups flour
    - **2** cups butter
    - **2** cups sugar
    - **4** eggs
    - **2** bags chocolate chips ...
  - Place on sheet and bake for about **10** minutes.

# Parameterized recipe

- Recipe for baking **20** cookies:
  - Mix the following ingredients in a bowl:
    - **4** cups flour
    - **1** cup sugar
    - **2** eggs
    - ...
- Recipe for baking **N** cookies:
  - Mix the following ingredients in a bowl:
    - **N/5** cups flour
    - **N/20** cups butter
    - **N/20** cups sugar
    - **N/10** eggs
    - **N/20** bags chocolate chips ...
  - Place on sheet and bake for about **10** minutes.
- **parameter:** A variable that distinguishes similar tasks.

# Redundant figures

- Consider the task of printing the following lines/boxes:

\* \* \* \* \*

\* \* \* \* \*

\* \* \* \* \*

\* \* \*

\* \* \* \* \*

\* \* \* \* \*

\* \* \*

\* \* \*

100

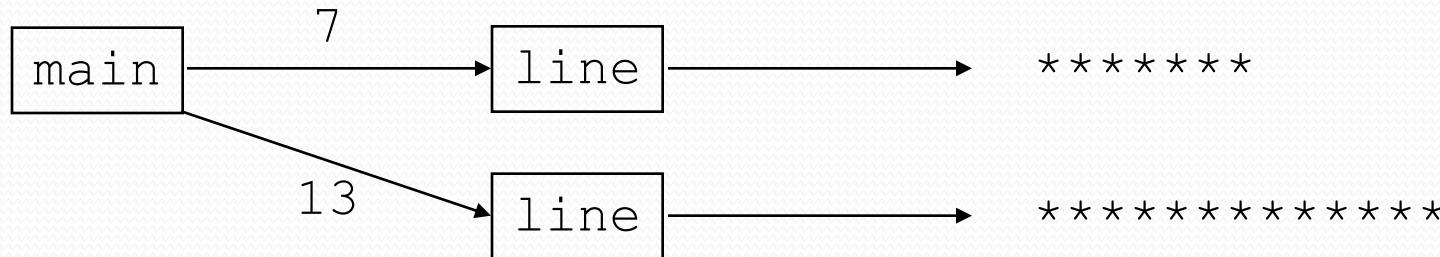

# A redundant solution

```
public class Stars1 {  
    public static void main(String[] args) {  
        lineOf13();  
        lineOf7();  
        lineOf35();  
        box10x3();  
        box5x4();  
    }  
  
    public static void lineOf13() {  
        for (int i = 1; i <= 13; i++) {  
            System.out.print("*");  
        }  
        System.out.println();  
    }  
  
    public static void lineOf7() {  
        for (int i = 1; i <= 7; i++) {  
            System.out.print("*");  
        }  
        System.out.println();  
    }  
  
    public static void lineOf35() {  
        for (int i = 1; i <= 35; i++) {  
            System.out.print("*");  
        }  
        System.out.println();  
    }  
    ...  
}
```

- This code is redundant.
- Would variables help?  
Would constants help?
- What is a better solution?
  - line - A method to draw a line of any number of stars.
  - box - A method to draw a box of any size.

# Parameterization

- **parameter:** Something passed to a method by its caller
  - Instead of `lineOf7`, `lineOf13`, write `line` to draw any length.
    - When *declaring* the method, we will state that it requires a parameter for the number of stars.
    - When *calling* the method, we will specify how many stars to draw.

- A parameter is a variable with a slight twist:
  - Declared by a method; in scope for entire method
  - *Initialized by each call to the method*

# Declaring a parameter

*Stating that a method requires a parameter in order to run*

```
public static void name ( type name ) {  
    statement(s);  
}
```

- **Example:**

```
public static void sayPassword(int code) {  
    System.out.println("The password is: " + code);  
}
```

- When `sayPassword` is called, the caller must specify the integer code to print (i.e., initialize the parameter variable).

# Passing parameters

*Calling a method and specifying values for its parameters*

**name (expression) ;**

This does the initialization; there is no = involved

- Example:

```
public static void main(String[] args) {  
    sayPassword(42);  
    sayPassword(12345);  
}
```

Output:

The password is 42

The password is 12345

# Parameters and loops

- A parameter can guide the number of repetitions of a loop.

```
public static void main(String[] args) {  
    chant(3);  
}
```

```
public static void chant(int times) {  
    for (int i = 1; i <= times; i++) {  
        System.out.println("Just a salad...");  
    }  
}
```

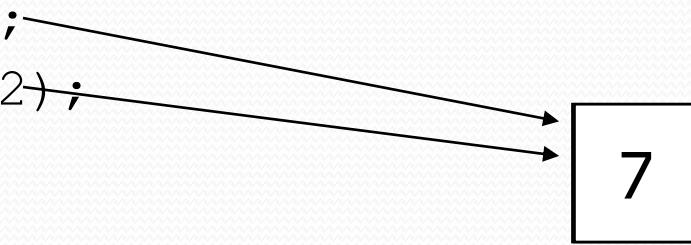

## Output:

```
Just a salad...  
Just a salad...  
Just a salad...
```

# How parameters are passed

- When the method is called:
  - The value is stored into the parameter variable.
  - The method's code executes using that value.

```
public static void main(String[] args) {  
    int x = 5;  
    chant(3);  
    chant(x+2);  
}
```

The diagram shows two arrows originating from the arguments in the main() call. One arrow points from the value 3 to a square box containing the number 7. Another arrow points from the expression x+2 to the same box. This illustrates how the value of x (which is 5) is passed as an argument to the chant() method, and how the method's code uses this value.

```
public static void chant(int times) {  
    for (int i = 1; i <= times; i++) {  
        System.out.println("Just a salad...");  
    }  
}
```

# Common errors

- If a method accepts a parameter, it is illegal to call it without passing any value for that parameter.

```
chant();           // ERROR: parameter value required
```

- The value passed to a method must be of the correct type.

```
chant(3.7);      // ERROR: must be of type int
```

- Exercise: Change the Stars program to use a parameterized method for drawing lines of stars.

# Stars solution

```
// Prints several lines of stars.  
// Uses a parameterized method to remove redundancy.  
public class Stars2 {  
    public static void main(String[] args) {  
        line(13);  
        line(7);  
        line(35);  
    }  
  
    // Prints the given number of stars plus a line break.  
    public static void line(int count) {  
        for (int i = 1; i <= count; i++) {  
            System.out.print("*");  
        }  
        System.out.println();  
    }  
}
```

# Back to our mirror

- Our mirror program had “offensive redundancy”
  - Repeated code in topHalf() and bottomHalf()
  - Longer program and multiple places to “fix the same bug”
- What we want is a method to print a mirror line
  - a |, some spaces, a <>, some dots, a <>, some spaces, a |
  - But how many spaces and dots depends on what line
  - The line number can be the parameter!
    - No other good way to do it, which is why we copied last lecture

```
public static void topHalf() {  
    for (int i = 1; i <= SIZE; i++) {  
        mirrorLine(i);  
    }  
}  
  
public static void mirrorLine(int line) { ... }
```

# Multiple parameters

- A method can accept multiple parameters. (separate by , )
  - When calling it, you must pass values for each parameter.
- Declaration:

```
public static void name (type name, ..., type name) {  
    statement(s);  
}
```

- Call:  
**methodName** (**value**, **value**, ..., **value**);

# Multiple parameters example

```
public static void main(String[] args) {  
    printNumber(4, 9);  
    printNumber(17, 6);  
    printNumber(8, 0);  
    printNumber(0, 8);  
}  
  
public static void printNumber(int number, int count) {  
    for (int i = 1; i <= count; i++) {  
        System.out.print(number);  
    }  
    System.out.println();  
}
```

## Output:

```
44444444  
171717171717  
00000000
```

# Stars with a box method

```
// Prints several lines and boxes made of stars.  
// Third version with multiple parameterized methods.  
  
public class Stars3 {  
    public static void main(String[] args) {  
        line(13);  
        line(7);  
        line(35);  
        System.out.println();  
        box(10, 3);  
        box(5, 4);  
        box(20, 7);  
    }  
  
    // Prints the given number of stars plus a line break.  
    public static void line(int count) {  
        for (int i = 1; i <= count; i++) {  
            System.out.print("*");  
        }  
        System.out.println();  
    }  
    ...  
}
```

# Stars solution, cont'd.

...

```
// Prints a box of stars of the given size.  
public static void box(int width, int height) {  
    line(width);  
  
    for (int line = 1; line <= height - 2; line++) {  
        System.out.print("*");  
        for (int space = 1; space <= width - 2; space++) {  
            System.out.print(" ");  
        }  
        System.out.println("*");  
    }  
  
    line(width);  
}
```

}

# Value semantics

- Modifying the parameter will not affect the caller's variables, even those used to initialize the parameter.
  - Just like with other variables

```
public static void strange(int x) {  
    x = x + 1;  
    System.out.println("1. x = " + x);  
}
```

```
public static void main(String[] args) {  
    int x = 23; // a "totally different x variable"  
    strange(x);  
    System.out.println("2. x = " + x);  
    ...  
}
```

Output:

```
1. x = 24  
2. x = 23
```

# A "Parameter Mystery" problem

```
public class ParameterMystery {  
    public static void main(String[] args) {  
        int x = 5;  
        int y = 9;  
        int z = 2;  
  
        mystery(z, y, x);  
  
        mystery(y, x, z);  
    }  
  
    public static void mystery(int x, int z, int y) {  
        System.out.println(z + " " + y + " " + x);  
    }  
}
```

# Strings

- **string**: A sequence of text characters.

```
String name = "text";
```

```
String name = expression;
```

- Examples:

```
String name = "Marla Singer";
```

```
int x = 3;
```

```
int y = 5;
```

```
String point = "(" + x + ", " + y + ")";
```

# Strings as parameters

```
public class StringParameters {  
    public static void main(String[] args) {  
        String teacher1 = "Dan";  
        sayHello(teacher1);  
        sayHello("Alan");  
        sayHello(teacher1 + " and " + "Alan");  
    }  
  
    public static void sayHello(String name) {  
        System.out.println("Welcome, " + name);  
    }  
}
```

## Output:

```
Welcome, Dan  
Welcome, Alan  
Welcome, Dan and Alan
```

# A Better Stars solution

```
// Prints several lines and boxes made of stars.  
// Fourth version with String parameters.  
  
public class Stars4 {  
    public static void main(String[] args) {  
        line(13);  
        line(7);  
        line(35);  
        System.out.println();  
        box(10, 3);  
        box(5, 4);  
        box(20, 7);  
    }  
  
    // Prints the given number of stars plus a line break.  
    public static void line(int count) {  
        repeat("*", count);  
        System.out.println();  
    }  
  
    ...
```

# Stars solution, cont'd.

...

```
// Prints a box of stars of the given size.  
public static void box(int width, int height) {  
    line(width);  
  
    for (int line = 1; line <= height - 2; line++) {  
        System.out.print("*");  
        repeat(" ", width - 2);  
        System.out.println("*");  
    }  
    line(width);  
}  
  
// Prints the given String the given number of times.  
public static void repeat(String s, int times) {  
    for (int i = 1; i <= times; i++) {  
        System.out.print(s);  
    }  
}
```
