Typing and Correcting Chars

- What data structure would you use for this problem?
 - User types characters on the command line
 - Until she hits enter, the backspace key (<) can be used to "erase the previous character"

Sample

- | • <u>Action</u> | • <u>Result</u> |
|-----------------|-----------------|
| • type h | • h |
| • type e | • he |
| • type l | • hel |
| • type o | • helo |
| • type < | • hel |
| • type l | • hell |
| • type w | • hellw |
| • type < | • hell |
| • type < | • hel |
| • type < | • he |
| • type < | • h |
| • type i | • hi |

Analysis

- We need to store a sequence of characters
 - The order of the characters in the sequence is significant
 - Characters are added at the end of the sequence
 - We only can remove the most recently entered character
-
- We need a data structure that is *Last in, first out*, or LIFO – a *stack*
 - Many examples in real life: stuff on top of your desk, trays in the cafeteria, discard pile in a card game, ...

Stack Terminology

- *Top*: Uppermost element of stack,
 - first to be removed
- *Bottom*: Lowest element of stack,
 - last to be removed
- Elements are always inserted and removed from the top (LIFO)

18-6

Stack Operations

- `push(Object)`: Adds an element to top of stack, increasing stack height by one
- Object `pop()`: Removes topmost element from stack and returns it, decreasing stack height by one
- Object `top()`: Returns a copy of topmost element of stack, leaving stack unchanged
- No "direct access"
 - cannot index to a particular data item
- No convenient way to traverse the collection
 - Try it at home!

Picturing a Stack

- Stack pictures are usually somewhat abstract
- Not necessary to show "official" style of names, references, etc.
 - Unless asked to do so, or course!
- "Top" of stack can be up, down, left, right – just label it.

What is the result of...

```
Stack s;  
Object v1,v2,v3,v4,v5,v6;  
s.push("Yawn");  
s.push("Burp");  
v1 = s.pop();  
s.push("Wave");  
s.push("Hop");  
v2 = s.pop();  
s.push("Jump");  
v3 = s.pop();  
v4 = s.pop();  
v5 = s.pop();  
v6 = s.pop();
```

v1 v2 v3 v4 v5 v6

Stack Practice

- Show the changes to the stack in the following example:

```
Stack s;  
Object obj;  
s.push("abc");  
s.push("xyzyzy");  
s.push("secret");  
obj = s.pop();  
obj = s.top();  
s.push("swordfish");  
s.push("terces");
```

Stack Implementations

- Several possible ways to implement
 - An array
 - A linked listUseful thought problem: How would you do these?
- Easiest way in Java: implement with some sort of List
 - `push(Object) :: add(Object)`
 - `top() :: get(size() - 1)`
 - `pop() :: remove(size() - 1)`
 - Precondition for `top()` and `pop()`: stack not empty

What is the Appropriate Model?

- waiting lines in a grocery store...
- job flow on an assembly line...
- traffic flow at the airport....
- "Your call is important to us. Please stay on the line. Your call will be answered in the order received. Your call is important to us..."
 - ...
- Characteristics
 - Objects enter the line at one end (rear)
 - Objects leave the line at the other end (front)
- This is a "*first in, first out*" (FIFO) data structure.

Queue Definition

- Queue: Ordered collection, accessed only at the front (remove) and rear (insert)
 - Front: First element in queue
 - Rear: Last element of queue
- FIFO: First In, First Out
- Footnote: picture can be drawn in either direction

18-13

Abstract Queue Operations

- **insert**(Object) : Adds an element to rear of queue
 - succeeds unless the queue is full (if implementation is bounded)
 - often called "enqueue"
- Object **front**() : Return a copy of the front element of queue
 - precondition: queue is not empty
- Object **remove**() : Remove and return the front element of queue
 - precondition: queue is not empty
 - often called "dequeue"

Queue Example

- Draw a picture and show the changes to the queue in the following example:

Queue q; Object v1, v2;

```
q.insert("chore");
q.insert("work");
q.insert("play");
v1 = q.remove();
v2 = q.front();
q.insert("job");
q.insert("fun");
```

What is the result of:

Queue q; Object v1,v2,v3,v4,v5,v6

```
q.insert("Sue");
q.insert("Sam");
q.insert("Sarah");
v1 = q.remove();
v2 = q.front();
q.insert("Seymour");
v3 = q.remove();
v4 = q.front();
q.insert("Sally");
v5 = q.remove();
v6 = q.front();
```

Queue Implementations

- Similar to stack
 - Array – trick here is what do you do when you run off the end
 - Linked list – ideal, if you have both a *first* and a *last* pointer.
- Easiest way in Java: use LinkedList class
 - `insert(Object):: addLast(Object)` [or `add(Object)`]
 - `getFront():: getFirst()`
 - `remove():: removeFirst()`
 - Interesting "coincidence" that a Java LinkedList supports exactly the operations you want to implement queues.

Bounded vs Unbounded

- In the abstract, queues and stacks are generally thought of as "unbounded": no limit to the number of items that can be inserted.
- In some practical applications, only a finite size can be accommodated: "bounded".
- Assume "unbounded" unless you hear otherwise.
- When the boundedness of a queue is an issue, it is sometimes called a "buffer"
 - People speak of bounded buffers and unbounded buffers
 - Frequent applications in systems programming

Summary

- Stacks and Queues
 - Specialized list data structures for particular applications
- Stack
 - LIFO (Last in, first out)
 - Operations: push(Object), top(), and pop()
- Queue
 - FIFO (First in, first out)
 - Operations: insert(Object), getFront(), and remove()
- Implementations: arrays or lists are possibilities for each
- Next up: applications of stacks and queues
