

## Turing Machines Review

---

- ◆ An example of a decidable language that is not a CFL
  - ⇒ Implementation-level description of a TM
  - ⇒ State diagram of TM
- ◆ Varieties of TMs
  - ⇒ Multi-Tape TMs
  - ⇒ Nondeterministic TMs
  - ⇒ String Enumerators

## Turing Machines

---

Just like a DFA except:

- ⇒ You have an infinite “tape” memory (or scratchpad) on which you receive your input and on which you can do your calculations
- ⇒ You can read one symbol at a time from a cell on the tape, write one symbol, then move the read/write pointer (head) left (L) or right (R)

## Who's Turing?

R. Rao, CSE 322

- ◆ Alan Turing (1912-1954): one of the most brilliant mathematicians of the 20<sup>th</sup> century (one of the “founding fathers” of computing)
- ◆ Click on “Theory Hall of Fame” link on class web under “Lectures”
- ◆ Introduced the Turing machine as a formal model of what it means to compute and solve a problem (i.e. an “algorithm”)
  - ⇒ Paper: On computable numbers, with an application to the Entscheidungsproblem, Proc. London Math. Soc. 42 (1936).

3

## How do Turing Machines compute?

- ◆  $\delta(\text{current state, symbol under the head}) = (\text{next state, symbol to write over current symbol, direction of head movement})$

- ◆ Diagram shows:  $\delta(q_1, 1) = (q_{rej}, 0, L)$  (R = right, L = left)
- ◆ In terms of “Configurations”:  $110q_110 \Rightarrow 11q_{rej}000$

## Solving Problems with Turing Machines

---

- ◆ We know  $L = \{0^n 1^n 0^n \mid n \geq 0\}$  is not a CFL (pumping lemma)
- ◆ Show  $L$  is decidable
  - ⇒ Construct a decider  $M$  such that  $L(M) = L$
  - ⇒ A **decider** is a TM that always halts (in  $q_{acc}$  or  $q_{rej}$ ) and is *guaranteed not to go into an infinite loop for any input*

## Idea for a Decider for $\{0^n 1^n 0^n \mid n \geq 0\}$

---

- ◆ **General Idea:** Match each 0 with a 1 and a 0 following the 1.
- ◆ Implementation Level Description of a Decider for  $L$ :  
On input  $w$ :
  1. If first symbol = blank, ACCEPT
  2. If first symbol = 1, REJECT
  3. If first symbol = 0, Write a blank to mark left end of tape
    - a. If current symbol is 0 or X, skip until it is 1. REJECT if blank.
    - b. Write X over 1. Skip 1's/X's until you see 0. REJECT if blank.
    - c. Write X over 0. Move back to left end of tape.
  4. At left end: Skip X's until:
    - a. You see 0: Write X over 0 and **GOTO** 3a
    - b. You see 1: REJECT
    - c. You see a blank space: ACCEPT

## State Diagram

- ◆ Try running the decider on:
  - ⇒ 010, 001100, ... → ACCEPT
  - ⇒ 0, 000, 0100, ... → REJECT
  - ⇒ What about 010010?

Houston, we have a  
problem with our  
Turing machine...

## What's the problem?

- ◆ The decider accepts incorrect strings:
  - ⇒ 010010, 010001100 → ACCEPT!!!
  - ⇒ Accepts  $(0^n 1^n 0^n)^*$

E. W. Dijkstra

Maybe  
it's the  
**GOTO?**

## An Aside: Dijkstra on GOTOs

“For a number of years I have been familiar with the observation that the quality of programmers is a decreasing function of the density of go to statements in the programs they produce.”

Opening sentence of: “*Go To Statement Considered Harmful*” by Edsger W. Dijkstra, Letter to the Editor, Communications of the ACM, Vol. 11, No. 3, March 1968, pp. 147-148.

## A Simple Fix (to the Decider)

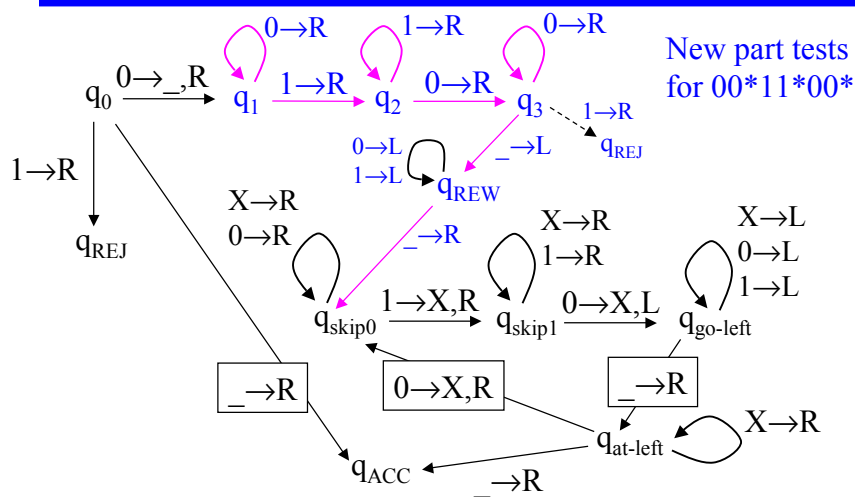

- ◆ Scan initially to make sure string is of the form  $0^*1^*0^*$
- ◆ On input  $w$ :
  1. If first symbol = blank, ACCEPT
  2. If first symbol = 1, REJECT
  3. If first symbol = 0: **if  $w$  is not in  $00^*11^*00^*$ , REJECT; else,** Write a blank to mark left end of tape
    - a. If current symbol is 0 or X, skip until it is 1. REJECT if blank.
    - b. Write X over 1. Skip 1's/X's until you see 0. REJECT if blank.
    - c. Write X over 0. Move back to left end of tape.
  4. At left end: Skip X's until:
    - a. You see 0: Write X over 0 and GOTO 3a
    - b. You see 1: REJECT
    - c. You see a blank space: ACCEPT

← Add this

GOTO okay here...

## The Decider TM for L in all its glory

## Varieties of TMs

---

What if we allow multiple tapes?

What if we allow nondeterminism?

What if I take nap?

## Various Types of TMs

---

- ◆ **Multi-Tape TMs:** TM with  $k$  tapes and  $k$  heads
  - ⇒  $\delta: Q \times \Gamma^k \rightarrow Q \times \Gamma^k \times \{L,R\}^k$
  - ⇒  $\delta(q_i, a_1, \dots, a_k) = (q_j, b_1, \dots, b_k, L, R, \dots, L)$
- ◆ **Nondeterministic TMs (NTMs)**
  - ⇒  $\delta: Q \times \Gamma \rightarrow \text{Pow}(Q \times \Gamma \times \{L,R\})$
  - ⇒  $\delta(q_i, a) = \{(q_1, b, R), (q_2, c, L), \dots, (q_m, d, R)\}$
- ◆ **Enumerator TM for  $L$ :** Prints all strings in  $L$  (in any order, possibly with repetitions) and only the strings in  $L$
- ◆ Other types: TM with Two-way infinite tape, TM with multiple heads on a single tape, 2D infinite tape TM, Random Access Memory (RAM) TM, etc.

## Surprise! All TMs are born equal...

- ◆ Each of the preceding TMs is equivalent to the standard TM
  - ⇒ They recognize the same set of languages (the Turing-recognizable languages)
- ◆ Proof idea: Simulate the “deviant” TM using a standard TM
- ◆ **Example 1: Multi-tape TM on a standard TM**
  - ⇒ Represent  $k$  tapes sequentially on 1 tape using separators #
  - ⇒ Use new symbol  $\underline{a}$  to denote a head currently on symbol  $a$

(See text for details)

## Example 2: Simulating Nondeterminism

- ◆ Any nondeterministic TM  $N$  can be simulated by a deterministic TM  $M$ 
  - ⇒ NTMs:  $\delta: Q \times \Gamma \rightarrow \text{Pow}(Q \times \Gamma \times \{L, R\})$
  - ⇒ No  $\epsilon$  transitions but can simulate them by reading and writing same symbol
  - ⇒  $N$  accepts  $w$  iff there is at least 1 path in  $N$ 's tree for  $w$  ending in  $q_{\text{ACC}}$
- ◆ **General proof idea:** Simulate each branch sequentially
  - ⇒ **Proof idea 1:** Use depth first search? No, might go deep into an infinite branch and never explore other branches!
  - ⇒ **Proof idea 2:** Use breadth first search Explore all branches at depth  $n$  before  $n+1$

## Simulating Nondeterminism: Details, Details

- ◆ Use a 3-tape DTM  $M$  for breadth-first traversal of  $N$ 's tree on  $w$ :
  - ⇒ Tape 1 keeps the input string  $w$
  - ⇒ Tape 2 stores  $N$ 's tape during simulation along 1 path (given by tape 3) up to a particular depth, starting with  $w$
  - ⇒ Tape 3 stores current path number  
E.g.  $\epsilon$  = root node  $q_0$   
213 = path made up of 3<sup>rd</sup> child of 1<sup>st</sup> child of 2<sup>nd</sup> child of root
- ◆ See text for more details

Next Class: We'll 'rap up Chapt 3 and cova' undecidability...

Can't wait for undecidability!

That guy needs help...

Have a great weekend!
