User Interfaces & Event-Driven Programs

---

# Graphical User Interfaces (GUIs)

---

- Large and important class of event-driven programs
  - waits for user-interaction events
  - mouse clicks, button presses, etc.
- Desktop, Mobile, Web, etc. provide libraries to write these
  - each of these use callbacks & events
  - examples of “event-driven programs”
- Using these libraries decreases bugs
  - also gives users a familiar experience

# GUI Libraries

---

- Core parts of these applications:
  - stores some data for the user
  - displays that data for the user
  - allows the user to change the data
    - causes the app to re-display
- Early apps required a lot of code to implement these
- More recent improvements have made this easier
  - highly valuable
    - your time is important
  - less code (usually) means fewer bugs

# GUI Libraries

---

- AWT & Swing are the native Java libraries for writing GUIs
  - Android apps are also GUIs and written in Java
- Core parts of these applications:
  - stores some data for the user
  - displays that data for the user
  - allows the user to change the data
    - causes the app to re-display
- Library helps with the latter two parts
  - components used to display data
  - components allow *listeners* that are notified of interaction

# AWT / Swing Example

---

SimpleFieldDemo.java

# Events in GUI Libraries

---

Most of the GUI widgets can generate events

- button clicks, menu picks, key press, etc.

Add a **listener** to be called back when those events occur

- component promises to call you in those circumstances
- passed an **event** object that provides info about the event

More examples of “callbacks” coming later...

# Achievement unlocked: Callbacks

---

*Callback pattern*: “Code” provided by client to be used by library

- In JS etc., pass a function as an argument
- In Java, pass an object with the “code” in a method

Examples: `HashMap` calls its client’s `hashCode`, `equals`

*Synchronous* callbacks:

- Useful when library needs the callback result immediately

*Asynchronous* callbacks:

- *Register* to indicate interest and where to call back
- Useful when the callback should be performed later, when some interesting event occurs

# Event listeners / handlers

---

*Event listeners* must implement the proper interface. AWT/Swing:

**KeyListener** – handle key press

**ActionListener** – handle button press

**MouseListener** – handle mouse clicks

**MouseMotionListener** – handle mouse move/drag

When an event occurs

- the appropriate method specified in the interface is called:  
**actionPerformed**, **keyPressed**, **mouseClicked**,  
**mouseDragged**, ...
- an event object is passed to the listener method

Interfaces are different in Android but all conceptually the same

# Event objects

---

GUI event is represented by an *event object*

- passes information often needed by the handler

In AWT/Swing, the superclass is **AWTEvent**. Some subclasses are:

**ActionEvent** – GUI-button press

**KeyEvent** – keyboard

**MouseEvent** – mouse move/drag/click/button

In Android, the superclass is **InputEvent**.

Event objects contain

- UI object that triggered the event
- other information depending on event. Examples:

**ActionEvent** – text string from a button

**MouseEvent** – mouse coordinates

# Achievement unlocked: Observers

---

This is the *observer pattern*

- Objects can be *observed* via *observers/listeners* that are *notified via callbacks* when an *event* (of interest) occurs
- **Pattern**: Something used over-and-over in software, worth recognizing when appropriate and using common terms
- Widely used in public libraries

More examples of “observers” coming later...

# GUI Client Programming

---

- Clients sit around waiting for events like:
  - mouse move/drag/click, button press, button release
  - keyboard: key press or release, sometimes with modifiers like shift/control/alt/etc.
  - finger tap or drag on a touchscreen
  - window resize/minimize/restore/close
  - timer interrupt (including animations)
  - network activity or file I/O (start, done, error)
    - (we will see an example of this shortly)

# Event-driven programming

---

An *event-driven* program is designed to wait for events:

- program initializes then enters the *event loop*
- abstractly:

```
do {  
    e = getNextEvent();  
    process event e;  
} while (e != quit);
```

Contrast with most programs we have written so far

- they perform specified steps in order and then exit
- that style is still used, just not as frequently
  - example: computing Page Rank or other Big Data work

# UI Thread

---

- Where is the event loop in these Swing programs?
- The library creates a separate thread that runs that event loop
  - the “UI thread”
  - created when the **JFrame** is made visible
  - application does not exit until this thread also finishes
    - that happens automatically when the window is closed

# Problems with SimpleFieldDemo

---

- Code is too **verbose**
  - can be improved using Lambda syntax
- Code is *not at all* **modular**
  - one file that mixes data, presentation, interaction
- **Too much work** involved with laying out elements

# Easier Layout Idea #1: Just Say No

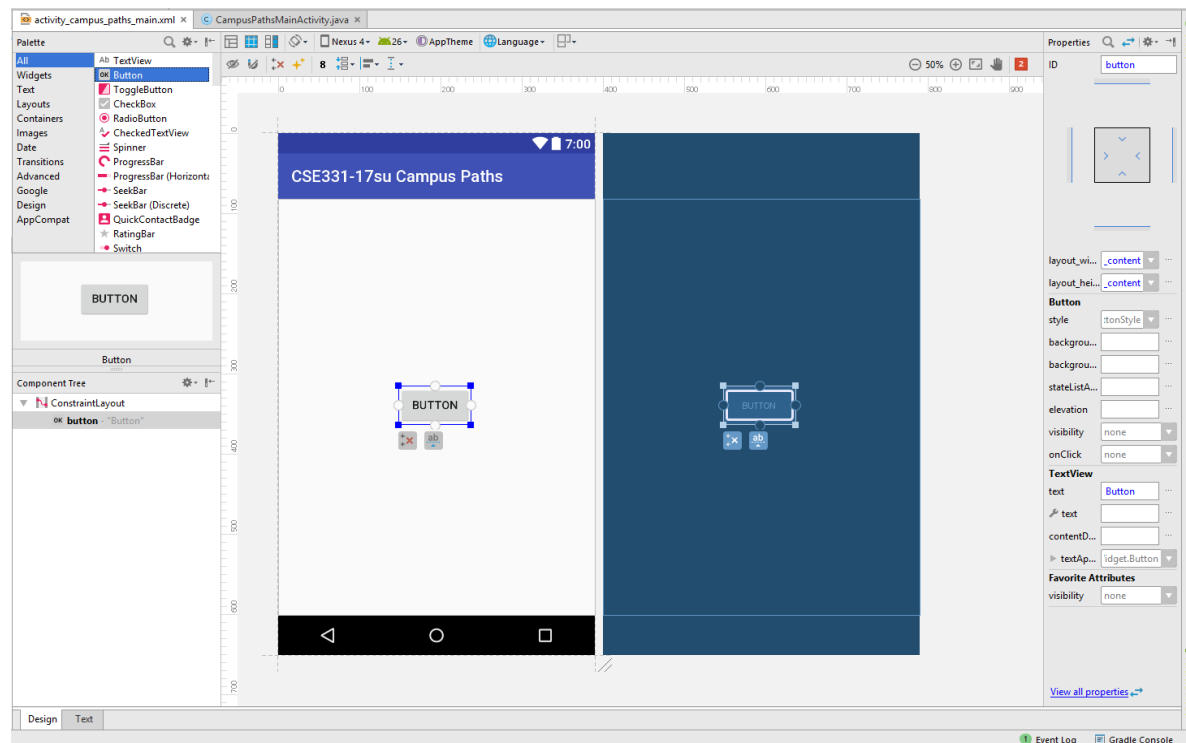

---

- Much of the difficulty here has to do with resizing...
- Do we really need to support resizing?
- Two platforms restrict resizing in some ways:
  - Android / iPhone
  - Bootstrap (HTML)

# iPhone / Android Layout

---

- iPhone and iPad come in fixed sizes
- Just give a fixed layout for each possible size

# Bootstrap (HTML)

---

- Width is restricted to one of 5 values (phone up to huge screen)
  - library automatically switches to best match for screen width
  - can use the same design for multiple sizes if you wish
- Still allows arbitrary height for the content

# Bootstrap Example

---

BootstrapDemo.html

# Easier Layout Idea #2: Declarative UI

---

- How much of layout needs to be code?
  - does this really require forward / backward reasoning?
- iPhone / Android show that this can be done
  - only for fixed sized screens
- HTML can be used as a more declarative language for UI
  - (.NET and other frameworks have comparable toolkits)

# HTML

---

- Hyper-Text Markup Language
- Language for writing documents shown in a web browser
  - co-opted to display the UI for Web apps
- Document is a sequence of tags and text

# Anatomy of a Tag

---

# Anatomy of a Tag

---

# Tags form a Tree

---

```
<div>
  <p id="firstParagraph"> Some Text </p>
  <br>
  <div>
    <p>Hello</p>
  </div>
</div>
```

This tree, as it lives in the browser, is often called the "DOM" – *Document Object Model*

# A Few Useful Tags

---

- See the W3Schools HTML reference for a complete list, along with all their supported attributes.
- Some worth knowing:
  - `<p>` - Paragraph tag, surrounds text with whitespace/line breaks.
  - `<div>` - “The curly braces of HTML” - used for grouping other tags. Surrounds its content with whitespace/line breaks.
  - `<span>` - Like `<div>`, but no whitespace/line breaks.
  - `<br />` - Forces a new line (like “\n”). Has no content.
  - `<html>` and `<head>` and `<body>` - Used to organize a basic HTML document.

# HTML for UI

---

- Consists tags and their content
  - components become tags
    - input fields, buttons, etc.
    - e.g., <button>
  - containers have start and end tags
    - tags placed in between are children
    - e.g., <div> and <p>
  - additional information provided to the tag with “attributes”
- HTML removes the need for `panel.add` calls
  - parent / child relationship *implied* by tree structure

# HTML + JS

---

- To make an app we also need **code**
- Code is provided inside a `<script>` tag
  - all browsers support the JavaScript language
  - more in a moment...

# HTML + JS UI Example

---

HtmlFieldDemo.html

# HTML + JS + CSS

---

- Cascading Style Sheets allow separation of styling from rest
  - **styling** is colors, margins, etc.
  - allows non-programmers to take some of this work
    - code produces document structure (tree of tags)
    - changes to tags require agreement by both parties

# Dynamic Web Content

---

- Earlier example had a fixed set of components.
  - same for iPhone / Android apps
- More realistic apps need to change the set of components displayed on the screen dynamically
  - consider Gmail as an example
  - need the components to come from code

# JS Example

---

register/index.js

# Remaining Problems

---

- ~~• Code is extremely **verbose**~~
  - ~~– can be improved using Lambdas~~
- Code is *not sufficiently modular*
  - one JS mixes data, display, interaction
- ~~• **Too much work** involved with laying out elements~~
- Poor **tool support**
  - HTML is created in strings!
  - (and other issues not mentioned so far...)
