CSE 341 : Programming Languages

Lecture 8 First Class Functions

Zach Tatlock Spring 2014

What is functional programming?

"Functional programming" can mean a few different things:

- 1. Avoiding mutation in most/all cases (done and ongoing)
- 2. Using functions as values (this unit)

. . .

- Style encouraging recursion and recursive data structures
- Style closer to mathematical definitions
- Programming idioms using *laziness* (later topic, briefly)
- Anything not OOP or C? (not a good definition)

Not sure a definition of "*functional language*" exists beyond "makes functional programming easy / the default / required"

- No clear yes/no for a particular language

2

First-class functions

- First-class functions: Can use them wherever we use values
 - Functions are values too
 - Arguments, results, parts of tuples, bound to variables, carried by datatype constructors or exceptions, ...

```
fun double x = 2*x
fun incr x = x+1
val a_tuple = (double, incr, double(incr 7))
```

- Most common use is as an argument / result of another function
 - Other function is called a *higher-order function*
 - Powerful way to factor out common functionality

Function Closures

- *Function closure*: Functions can use bindings from outside the function definition (in scope where function is defined)
 - Makes first-class functions much more powerful
 - Will get to this feature in a bit, after simpler examples
- Distinction between terms *first-class functions* and *function closures* is not universally understood
 - Important conceptual distinction even if terms get muddled

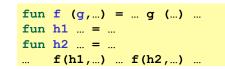

Onward

The next week:

- How to use first-class functions and closures
- The precise semantics
- Multiple powerful idioms

Functions as arguments

We can pass one function as an argument to another function
 Not a new feature, just never thought to do it before

Elegant strategy for factoring out common code
Replace *N* similar functions with calls to 1 function where you pass in *N* different (short) functions as arguments

[See the code file for this lecture]

Example

Can reuse n_times rather than defining many similar functions

- Computes f(f(...f(x))) where number of calls is n

```
fun n_times (f,n,x) =
    if n=0
    then x
    else f (n_times(f,n-1,x))
fun double x = x + x
fun increment x = x + 1
val x1 = n_times(double,4,7)
val x2 = n_times(increment,4,7)
val x3 = n_times(t1,2,[4,8,12,16])
```

```
fun double_n_times (n,x) = n_times(double,n,x)
fun nth_tail (n,x) = n_times(tl,n,x)
```

Relation to types

- Higher-order functions are often so "generic" and "reusable" that they have polymorphic types, i.e., types with type variables
- · But there are higher-order functions that are not polymorphic
- And there are non-higher-order (first-order) functions that are polymorphic
- Always a good idea to understand the type of a function, especially a higher-order function

5

6

Types for example

```
fun n_times (f,n,x) =
    if n=0
    then x
    else f (n_times(f,n-1,x))
```

- Two of our examples instantiated 'a with int
- One of our examples instantiated 'a with int list
- This polymorphism makes n_times more useful
- Type is *inferred* based on how arguments are used (later lecture)
 - Describes which types must be exactly something (e.g., int) and which can be anything but the same (e.g., 'a)

9

Polymorphism and higher-order functions

- Many higher-order functions are polymorphic because they are so reusable that some types, "can be anything"
- But some polymorphic functions are not higher-order
 Example: len : 'a list -> int
- And some higher-order functions are not polymorphic
 Example: times until 0 : (int -> int) * int -> int

```
fun times_until_0 (f,x) =
    if x=0 then 0 else 1 + times_until_0(f, f x)
```

Note: Would be better with tail-recursion

10

Toward anonymous functions

• Definitions unnecessarily at top-level are still poor style:

```
fun triple x = 3*x
fun triple_n_times (f,x) = n_times(triple,n,x)
```

• So this is better (but not the best):

```
fun triple_n_times (f,x) =
  let fun trip y = 3*y
  in
    n_times(trip,n,x)
  end
```

- · And this is even smaller scope
 - It makes sense but looks weird (poor style; see next slide)

```
fun triple_n_times (f,x) =
  n_times(let fun trip y = 3*y in trip end, n, x)
```

Anonymous functions

This does not work: A function binding is not an expression

fun triple_n_times (f,x) =
 n times((fun trip y = 3*y), n, x)

 This is the best way we were building up to: an expression form for anonymous functions

```
fun triple_n_times (f,x) =
  n_times((fn y => 3*y), n, x)
```

- Like all expression forms, can appear anywhere
- Syntax:
 - fn NOt fun
 - => not =
 - · no function name, just an argument pattern

Using anonymous functions

- Most common use: Argument to a higher-order function
 - Don't need a name just to pass a function
- But: Cannot use an anonymous function for a recursive function
 - Because there is no name for making recursive calls
 - If not for recursion, fun bindings would be syntactic sugar for val bindings and anonymous functions

fun triple x = 3*xval triple = fn y => 3*y

A style point

Compare:

if x then true else false

With:

(fn x => f x)

So don't do this:

n_times((fn y => tl y),3,xs)

When you can do this:

n_times(t1,3,xs)

14

Мар

fun map (f,xs) =
 case xs of
 [] => []
 | x::xs' => (f x)::(map(f,xs'))

val map : ('a -> 'b) * 'a list -> 'b list

Map is, without doubt, in the "higher-order function hall-of-fame"

- The name is standard (for any data structure)
- You use it all the time once you know it: saves a little space, but more importantly, communicates what you are doing
- Similar predefined function: List.map
 - But it uses currying (coming soon)

Filter

```
fun filter (f,xs) =
    case xs of
    [] => []
    | x::xs' => if f x
        then x::(filter(f,xs'))
        else filter(f,xs')
```

val filter : ('a -> bool) * 'a list -> 'a list

Filter is also in the hall-of-fame

- So use it whenever your computation is a filter
- Similar predefined function: List.filter
 - But it uses currying (coming soon)

13

Generalizing

Our examples of first-class functions so far have all:

- Taken one function as an argument to another function
- Processed a number or a list

But first-class functions are useful anywhere for any kind of data

- Can pass several functions as arguments
- Can put functions in data structures (tuples, lists, etc.)
- Can return functions as results
- Can write higher-order functions that traverse your own data structures

Useful whenever you want to abstract over "what to compute with"

- No new language features

Returning functions

- Remember: Functions are first-class values
 For example, can return them from functions
- Silly example: fun double_or_triple f = if f 7 then fn x => 2*x else fn x => 3*x

Has type (int -> bool) -> (int -> int)

But the REPL prints (int -> bool) -> int -> int because it never prints unnecessary parentheses and t1 -> t2 -> t3 -> t4 means t1->(t2->(t3->t4))

18

17

Other data structures

- Higher-order functions are not just for numbers and lists
- They work great for common recursive traversals over your own data structures (datatype bindings) too
- Example of a higher-order *predicate*:
 - Are all constants in an arithmetic expression even numbers?
 - Use a more general function of type
 - (int -> bool) * exp -> bool
 - And call it with (fn $x \Rightarrow mod 2 = 0$)

19
