# CSE 341 Programming Languages

Implementing PLs

Zach Tatlock Spring 2014

**Rest of implementation** 

## Interpreter or compiler

So "rest of implementation" takes the abstract syntax tree (AST) and "runs the program" to produce a result

Fundamentally, two approaches to implement a PL *B*:

- Write an interpreter in another language *A* 
  - Better names: evaluator, executor
  - Take a program in *B* and produce an answer (in *B*)
- Write a compiler in another language *A* to a third language *C* 
  - Better name: translator
  - Translation must *preserve meaning* (equivalence)

We call *A* the metalanguage

- Crucial to keep A and B straight

## Reality more complicated

Evaluation (interpreter) and translation (compiler) are your options

– But in modern practice have both and multiple layers

A plausible example:

- Java compiler to bytecode intermediate language
- Have an interpreter for bytecode (itself in binary), but compile frequent functions to binary at run-time
- The chip is itself an interpreter for binary
  - Well, except these days the x86 has a translator in hardware to more primitive micro-operations it then executes

Racket uses a similar mix

#### Sermon

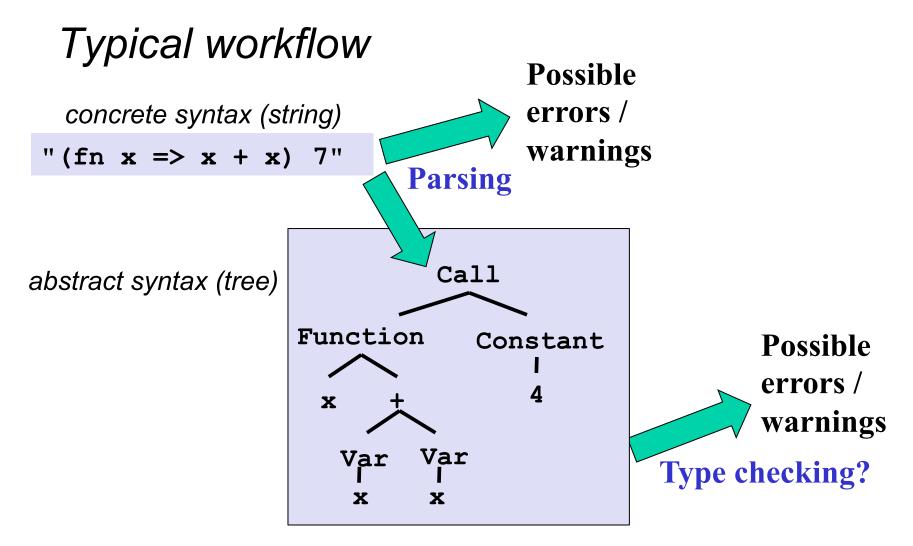

Interpreter versus compiler versus combinations is about a particular language **implementation**, not the language **definition** 

So there is no such thing as a "compiled language" or an "interpreted language"

- Programs cannot "see" how the implementation works

Unfortunately, you often hear such phrases

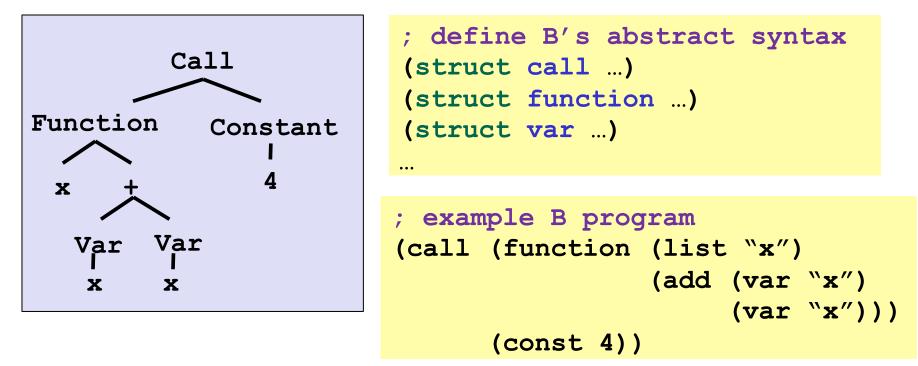

- "C is faster because it's compiled and LISP is interpreted"
- This is nonsense; politely correct people
- (Admittedly, languages with "eval" must "ship with some implementation of the language" in each program)

**Interpreter or translater** 

## Skipping parsing

- If implementing PL B in PL A, we can skip parsing
  - Have B programmers write ASTs directly in PL A
  - Not so bad with ML constructors or Racket structs
  - Embeds B programs as trees in A

#### Already did an example!

- Let the metalanguage *A* = Racket
- Let the language-implemented *B* = "*Arithmetic Language*"
- Arithmetic programs written with calls to Racket constructors
- The interpreter is eval-exp

```
(struct const (int) #:transparent)
(struct negate (e) #:transparent)
(struct add (el e2) #:transparent)
(struct multiply (el e2) #:transparent)
(define (eval-exp e)
  (cond [(const? e) e]
    [(negate? e)
    (const (- (const-int
                (eval-exp (negate-e e)))))]
    [(add? e) ...]
    [(multiply? e) ...]...
```

## What we know

- Define (abstract) syntax of language *B* with Racket structs
  - B called MUPL in homework
- Write *B* programs directly in Racket via constructors
- Implement interpreter for *B* as a (recursive) Racket function

Now, a subtle-but-important distinction:

- Interpreter can assume input is a "legal AST for B"
  - Okay to give wrong answer or inscrutable error otherwise
- Interpreter *must check* that recursive results are the right kind of *value*
  - Give a good error message otherwise

## Legal ASTs

• "Trees the interpreter must handle" are a subset of all the trees Racket allows as a dynamically typed language

```
(struct const (int) #:transparent)
(struct negate (e) #:transparent)
(struct add (e1 e2) #:transparent)
(struct multiply (e1 e2) #:transparent)
```

- Can assume "right types" for struct fields
  - const holds a number
  - negate holds a legal AST
  - add and multiply hold 2 legal ASTs
- Illegal ASTs can "crash the interpreter" this is fine

```
(multiply (add (const 3) "uh-oh") (const 4))
(negate -7)
```

#### Interpreter results

- Our interpreters return expressions, but not any expressions
  - Result should always be a *value*, a kind of expression that evaluates to itself
  - If not, the interpreter has a bug
- So far, only values are from const, e.g., (const 17)
- But a larger language has more values than just numbers
  - Booleans, strings, etc.
  - Pairs of values (definition of value recursive)
  - Closures
  - ...

## Example

See code for language that adds booleans, number-comparison, and conditionals:

```
(struct bool (b) #:transparent)
(struct eq-num (e1 e2) #:transparent)
(struct if-then-else (e1 e2 e3) #:transparent)
```

What if the program is a legal AST, but evaluation of it tries to use the wrong kind of value?

- For example, "add a boolean"
- You should detect this and give an error message not in terms of the interpreter implementation
- Means checking a recursive result whenever a particular kind of value is needed
  - No need to check if any kind of value is okay

## Dealing with variables

- Interpreters so far have been for languages without variables
  - No let-expressions, functions-with-arguments, etc.
  - Language in homework has all these things
- This segment describes in English what to do
  - Up to you to translate this to code
- Fortunately, what you have to implement is what we have been stressing since the very, very beginning of the course

## Dealing with variables

- An environment is a mapping from variables (Racket strings) to values (as defined by the language)
  - Only ever put pairs of strings and values in the environment
- Evaluation takes place in an environment
  - Environment passed as argument to interpreter helper function
  - A variable expression looks up the variable in the environment
  - Most subexpressions use same environment as outer expression
  - A let-expression evaluates its body in a larger environment

#### The Set-up

So now a recursive helper function has all the interesting stuff:

```
(define (eval-under-env e env)
  (cond ... ; case for each kind of
  )) ; expression
```

- Recursive calls must "pass down" correct environment

Then **eval-exp** just calls **eval-under-env** with same expression and the *empty environment* 

On homework, environments themselves are just Racket lists containing Racket pairs of a string (the MUPL variable name, e.g., "x") and a MUPL value (e.g., (int 17))

## A grading detail

- Stylistically eval-under-env would be a helper function one could define locally inside eval-exp
- But do not do this on your homework
  - We have grading tests that call eval-under-env directly, so we need it at top-level

## The best part

- The most interesting and mind-bending part of the homework is that the language being implemented has first-class closures
  - With lexical scope of course
- Fortunately, what you have to implement is what we have been stressing since we first learned about closures...

## Higher-order functions

The "magic": How do we use the "right environment" for lexical scope when functions may return other functions, store them in data structures, etc.?

Lack of magic: The interpreter uses a closure data structure (with two parts) to keep the environment it will need to use later

(struct closure (env fun) #:transparent)

Evaluate a function expression:

- A function is not a value; a closure is a value
  - Evaluating a function returns a closure
- Create a closure out of (a) the function and (b) the current environment when the function was evaluated

Evaluate a function call:

- ...

### Function calls

(call e1 e2)

- Use current environment to evaluate **e1** to a closure
  - Error if result is a value that is not a closure
- Use current environment to evaluate **e2** to a value
- Evaluate closure's function's body in the closure's environment, extended to:
  - Map the function's argument-name to the argument-value
  - And for recursion, map the function's name to the whole closure

This is the same semantics we learned a few weeks ago "coded up"

Given a closure, the code part is *only* ever evaluated using the environment part (extended), *not* the environment at the call-site

## Is that expensive?

- *Time* to build a closure is tiny: a struct with two fields
- Space to store closures *might* be large if environment is large
  - But environments are immutable, so natural and correct to have lots of sharing, e.g., of list tails (cf. lecture 3)
  - Still, end up keeping around bindings that are not needed
- Alternative used in practice: When creating a closure, store a possibly-smaller environment holding only the variables that are free variables in the function body
  - Free variables: Variables that occur, not counting shadowed uses of the same variable name
  - A function body would never need anything else from the environment

#### Free variables examples

 $(lambda () (+ x y z)) ; \{x, y, z\}$  $(lambda (x) (+ x y z)) ; \{y, z\}$  $(lambda (x) (if x y z)); \{y, z\}$  $(lambda (x) (let ([y 0]) (+ x y z))); \{z\}$ (lambda (x y z) (+ x y z)) ; {}  $(lambda (x) (+ y (let ([y z]) (+ y y)))); {y, z}$ 

## Computing free variables

- So does the interpreter have to analyze the code body every time it creates a closure?
- No: Before evaluation begins, compute free variables of every function in program and store this information with the function
- Compared to naïve store-entire-environment approach, building a closure now takes more time but less space
  - And time proportional to number of free variables
  - And various optimizations are possible
- [Also use a much better data structure for looking up variables than a list]

## Optional: compiling higher-order functions

- If we are compiling to a language without closures (like assembly), cannot rely on there being a "current environment"
- So compile functions by having the translation produce "regular" functions that *all* take an *extra explicit argument* called "environment"
- And compiler replaces all uses of free variables with code that looks up the variable using the environment argument
  - Can make these fast operations with some tricks
- Running program still creates closures and every function call passes the closure's environment to the closure's code

## Recall...

Our approach to language implementation:

- Implementing language *B* in language *A*
- Skipping parsing by writing language B programs directly in terms of language A constructors
- An interpreter written in *A* recursively evaluates

What we know about macros:

- Extend the syntax of a language
- Use of a macro expands into language syntax before the program is run, i.e., before calling the main interpreter function

## Put it together

With our set-up, we can use language *A* (i.e., Racket) *functions* that produce language *B* abstract syntax as language *B* "macros"

- Language B programs can use the "macros" as though they are part of language B
- No change to the interpreter or struct definitions
- Just a programming idiom enabled by our set-up
  - Helps teach what macros are
- See code for example "macro" definitions and "macro" uses
  - "macro expansion" happens before calling eval-exp

## Hygiene issues

- Earlier we had material on hygiene issues with macros
  - (Among other things), problems with shadowing variables when using local variables to avoid evaluating expressions more than once
- The "macro" approach described here does not deal well with this
