CSE341: Programming Languages
Lecture 14
Thunks, Laziness, Streams, Memoization

Eric Mullen Autumn 2019

## Delayed evaluation

For each language construct, the semantics specifies when
subexpressions get evaluated. In ML, Racket, Java, C
Function arguments are eager (call-by-value)

- Conditional branches are not eager

It matters: calling factorial-bad never terminates:
(define (my-if-bad xyz )
(if xy ) $)$
(if $x y z$ ))
(define (factorial-bad n$)$
(my-if-bad $=\mathrm{n}$
(my-if-bad ( $=\mathrm{n} 0$ )
${ }^{1}(* \mathrm{n}($ factorial-bad $\left.(-\mathrm{n} 1)))\right)$ )
Autumn 2019
CSE341: Proganming Languges $\qquad$

## Thunks delay

We know how to delay evaluation: put expression in a function

- Thanks to closures, can use all the same variables later

A zero-argument function used to delay evaluation is called a thunk

- As a verb: thunk the expression

This works (but it is silly to wrap if like this):
$\underset{(\text { if } \mathbf{x}(\mathbf{y})(\mathbf{z})) \text { ) }}{\text { (define }}$
(define (fact n)
(my-if ( $=\mathrm{n} 0$ )

(lambda() (* $\mathrm{n}($ fact $(-\mathrm{n} 1))))$ )
Autumn 2019 CSE341: Programming Languages

## The key point

- Evaluate an expression e to get a result:
e
- A function that when called, evaluates $\mathbf{e}$ and returns result - Zero-argument function for "thunking"
(lambda () e)
- Evaluate $e$ to some thunk and then call the thunk
(e)
- Next: Powerful idioms related to delaying evaluation and/or avoided repeated or unnecessary computations
- Some idioms also use mutation in encapsulated ways Autumn 2019 CSE341: Programming Languges

Avoiding expensive computations
Thunks let you skip expensive computations if they are not needed
Great if take the true-branch:

But worse if you end up using the thunk more than once:
(define ( $£$ th)
$(\ldots)$ (if (..)

(if (..) 0 (... (th) ...) ))
In general, might not know many times a result is needed
Autumn 2019
CSE341: Prognamming Languggs

## Best of both worlds

ssumin we would

- Not compute it until needed
- Remember the answer so future uses complete immediately Called lazy evaluation

Languages where most constructs, including function arguments, work this way are lazy languages

- Haskell

Racket predefines support for promises, but we can make our own

- Thunks and mutable pairs are enough
$\qquad$ Autumn 2019 CSE341: Programning Languages

```
Delay and force
    (define (my-delay th)
    (mcons #f th))
    (define (my-force p)
        (mcdr p)
            (set-mcar! P #t)
            (mcdr p)!))
```

An ADT represented by a mutable pair
- \#f in car means cdr is unevaluated thunk

- Really a one-of type: thunk or result-ofthun
    - Ideally hide representation in a module

CSEB4: Programming Langugec

## Lessons From Example

See code file for example that does multiplication using a very slow See code file for exam
additition helper function

With thunking second argument

- Great if first argument 0
- Okay if first argument 1
- Worse otherwise
- With precomputing second argument:
- Okay in all cases
- With thunk that uses a promise for second argument:
- Great if first argument 0
- Okay otherwise

## Streams

## Using streams

- A stream is an infinite sequence of values
- So cannot make a stream by making all the values
- Key idea: Use a thunk to delay creating most of the sequence - Just a programming idiom

A powerful concept for division of labor:

- Stream producer knows how to create any number of values

Stream consumer decides how many values to ask for
Some examples of streams you might (not) be familiar with:

- User actions (mouse clicks, etc.)
- UNIX pipes: cmd1 । cmd2 has cmd2 "pull" data from cmd1
- Output values from a sequential feedback circuit

We will represent streams using pairs and thunks
Let a stream be a thunk that when called returns a pair '(next-answer . next-thunk)

So given a stream s, the client can get any number of elements - First: (car (s))

- Second: (car ( (cdr (s))))
- Third: (car ((cdr ((cdr (s))))))
(Usually bind (cdr (s)) to a variable or pass to a recursive
function)

## Example using streams

This function returns how many stream elements it takes to find one for which tester does not return \#

- Happens to be written with a tail-recursive helper function
(define (number-until stream tester)
(letrec ([f (lambda (stream ans)
$\underset{\text { (if (tester (car pr) }}{\text { (lif }}$
$\underset{(\mathrm{f}}{\text { ans }(\text { (dr pr) }}(+$ ans 1$) 1) 1) 1)$
(f stream 1)) )
- (stream) generates the pair
- So recursively pass (cdr pr), the thunk for the rest of the infinite sequence
Autumn 2019
CSE341: Programming Languges

## Streams

Coding up a stream in your program is easy

- We will do functional streams using pairs and thunks

Let a stream be a thunk that when called returns a pair (next-answer . next-thunk)
Saw how to use them, now how to make them..

- Admittedly mind-bending, but uses what we know

Autumn 2019 CSE341: Programming Langugec

## Making streams

- How can one thunk create the right next thunk? Recursion! - Make a thunk that produces a pair where cdr is next thunk
- A recursive function can return a thunk where recursive call does not happen until thunk is called
(define ones (lambda () (cons 1 ones)))
define nats
(letrec ([f (lambda (x) (f) ( x (1)) )) )]
(lambda () $\begin{gathered}\left.\left(\begin{array}{l}\text { Cons } \\ (\mathrm{f} \\ \mathrm{I}\end{array}\right) \text { ) }\right)\end{gathered}$
(define powers-of-two
(letrec ( $f$ ( 1 ambda (

tunn 2019
CSE34: Progamnining Langagages

## Getting it wrong

- This uses a variable before it is defined
(define ones-really-bad (cons 1 ones-really-bad))
This goes into an infinite loop making an infinite-length list
(define ones-bad (lambda () cons 1 (ones-bad))) (define (ones-bad) (cons 1 (ones-bad)))
This is a stream: thunk that returns a pair with cdr a thunk (define ones (lambda () (cons 1 ones))) (define (ones) (cons 1 ones)

CSEB41: Progamming Langages

## Memoization

## How to do memoization: see example

- Need a (mutable) cache that all calls using the cache shar Need a (mutable) cache that all calls using the cache stan
- So must be defined outside the function(s) using it
- If a function has no side effects and does not read mutable memory, no point in computing it twice for the same arguments - Can keep a cache of previous results

Net win if (1) maintaining cache is
and (2) cached results are reused

- Similar to promises, but if the function takes arguments, then there are multiple "previous results"

For recursive functions, this memoization can lead to exponentially faster programs

- Related to algorithmic technique of dynamic programming

See code for an example with Fibonacci numbers

- Good demonstration of the idea because it is short, but, as shown in the code, there are also easier less-general ways to make fibonacci efficient
- (An association list (list of pairs) is a simple but sub-optimal data structure for a cache; okay for our example)

## assoc

Example uses assoc, which is just a library function you could look up in the Racket reference manual
(assoc v 1st) takes a list of pairs and locates the firs element of 1 st whose car is equal to v according to isequal l?. If such an element exists, the pair (i.e., an element of ) is returned. Othenwise the result is $\boldsymbol{\| f}$.

- Returns \#f for not found to distinguish from finding a pair with \#f in cdr
