Trees

CSE 373
Data Structures

Readings

- Reading
  - Goodrich and Tamassia, Chapter 6.

Why Do We Need Trees?

- Lists, Stacks, and Queues are linear relationships
- Information often contains hierarchical relationships
  - › File directories or folders
  - › Moves in a game
  - › Hierarchies in organizations
- Can build a tree to support fast searching

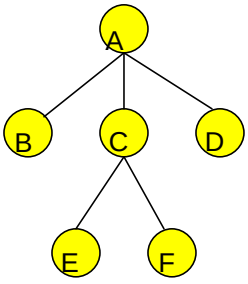
Tree Jargon

- root
- nodes and edges
- leaves

- parent, children, siblings
- ancestors, descendants

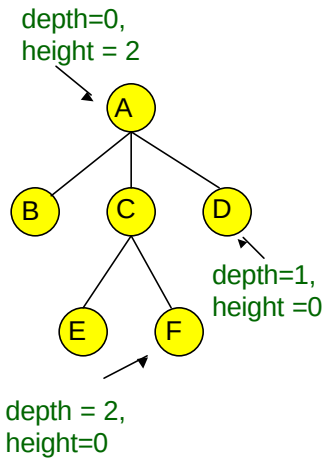
- subtrees

- path, path length
- height, depth



More Tree Jargon

- **Length** of a path = number of edges
- **Depth** of a node N = length of path from root to N
- **Height** of node N = length of longest path from N to a leaf
- **Depth of tree** = depth of deepest node
- **Height of tree** = height of root



Definition and Tree Trivia

- A tree is a set of nodes,i.e., either
  - it's an empty set of nodes, or
  - it has one node called the root from which zero or more trees (subtrees) descend
- Two nodes in a tree have at most one path between them
- Can a non-zero path from node N reach node N again?

No. Trees can never have cycles (loops)

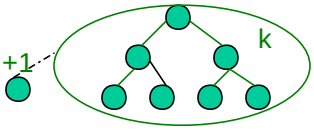
Paths

- A tree with N nodes always has N-1 edges (prove it by induction)

Base Case: N=1 one node, zero edges

Inductive Hypothesis: Suppose that a tree with N=k nodes always has k-1 edges.

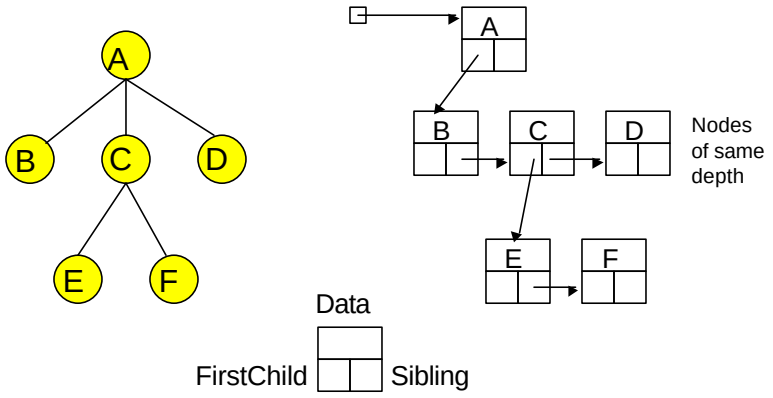
Induction: Suppose N=k+1…
The k+1st node must connect to the rest by 1 or more edges.
If more, we get a cycle. So it connects by just 1 more edge



Implementation of Trees

- One possible pointer-based Implementation
  - › tree nodes with value and a pointer to each child
  - › but how many pointers should we allocate space for?
- A more flexible pointer-based implementation
  - › 1st Child / Next Sibling List Representation
  - › Each node has 2 pointers: one to its first child and one to next sibling
  - › Can handle arbitrary number of children

Arbitrary Branching



Binary Trees

- Every node has at most two children
  - › Most popular tree in computer science
- Given N nodes, what is the minimum depth of a binary tree? (This means all levels but the last are full!)
  - › At depth d, you can have $N = 2^d$ to $N = 2^{d+1}-1$ nodes

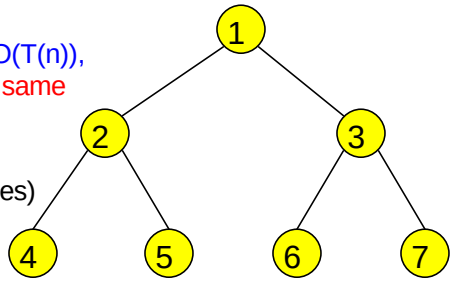
$$2^d \le N \le 2^{d+1} - 1 \quad \text{implies} \quad d_{min} = \lfloor \log_2 N \rfloor$$

Minimum depth vs node count

- At depth d, you can have N = 2^d to 2^{d+1}-1 nodes
- minimum depth d is Θ(log N)

T(n) = Θ(f(n)) means
T(n) = O(f(n)) and f(n) = O(T(n)),
i.e. T(n) and f(n) have the same growth rate

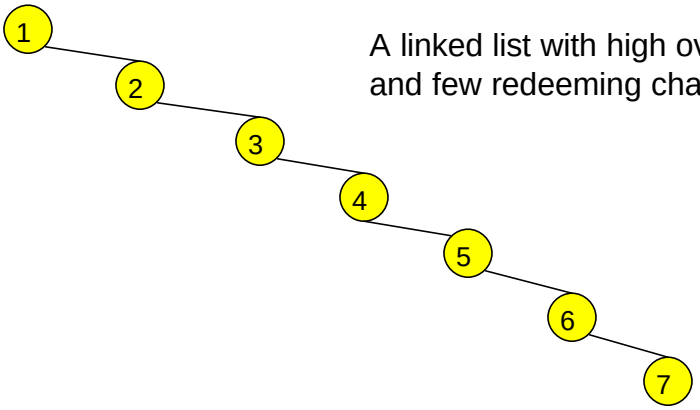
d=2
N=2^2 to 2^3-1 (i.e, 4 to 7 nodes)



Maximum depth vs node count

- What is the maximum depth of a binary tree?
  - › Degenerate case: Tree is a linked list!
  - › Maximum depth = N-1
- Goal: Would like to keep depth at around log N to get better performance than linked list for operations like Find

A degenerate tree



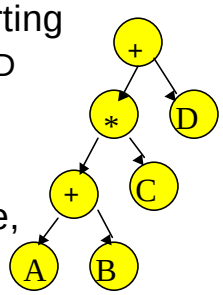
A linked list with high overhead and few redeeming characteristics

Traversing Binary Trees

- The definitions of the traversals are recursive definitions. For example:
  - Visit the root
  - Visit the left subtree (i.e., visit the tree whose root is the left child) and do this recursively
  - Visit the right subtree (i.e., visit the tree whose root is the right child) and do this recursively
- Traversal definitions can be extended to general (non-binary) trees

Traversing Binary Trees

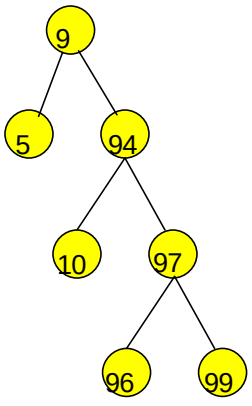
- Preorder: Node, then Children (starting with the left) recursively + * + A B C D



- Inorder: Left child recursively, Node, Right child recursively A + B * C + D
- Postorder: Children recursively, then Node
  A B + C * D +

Binary Search Trees

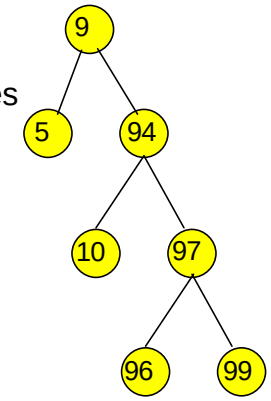
- Binary search trees are binary trees in which
  - › all values in the node's left subtree are less than node value
  - › all values in the node's right subtree are greater than node value
- Operations:
  - › Find, FindMin, FindMax, Insert, Delete



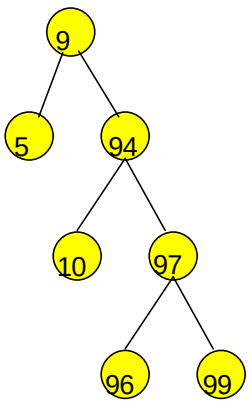
What happens when we traverse the tree in inorder?

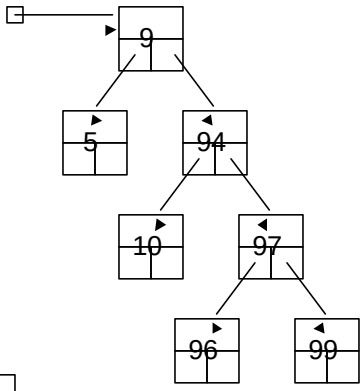
Operations on Binary Search Trees

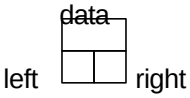
- How would you implement these?
  - › Recursive definition of binary search trees allows recursive routines
  - › Call by reference helps too
- FindMin
- FindMax
- Find
- Insert
- Delete



Binary SearchTree







Find

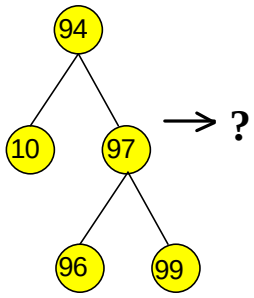
```
Find(T : tree pointer, x : element): tree pointer {
case {
  T = null : return null;
  T.data = x : return T;
  T.data > x : return Find(T.left,x);
  T.data < x : return Find(T.right,x)
}
}
```

FindMin

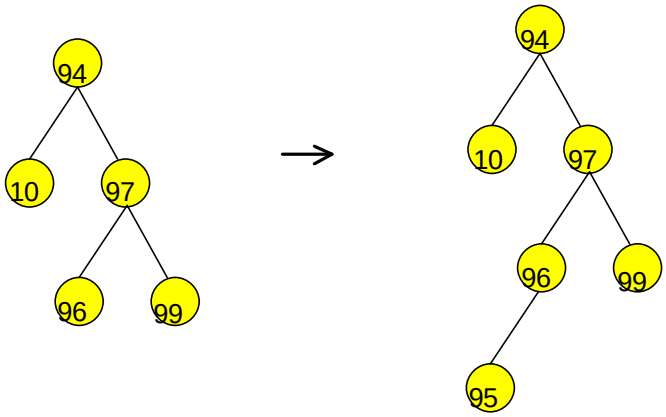
- Design recursive FindMin operation that returns the smallest element in a binary search tree.
  - `FindMin(T : tree pointer) : tree pointer {`
    `// precondition: T is not null //`
    `???`
    `}`

Insert Operation

- **`Insert(T: tree, X: element)`**
  - › Do a “Find” operation for X
  - › If X is found → update (no need to insert)
  - › Else, “Find” stops at a NULL pointer
  - › Insert Node with X there
- Example: Insert 95



Insert 95



Insert Done with call-by-reference

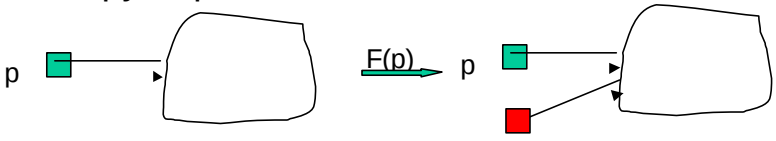
```
Insert(T : reference tree pointer, x : element) : integer {
if T = null then
  T := new tree; T.data := x; return 1;//the links to
                                       //children are null
case
  T.data = x : return 0;
  T.data > x : return Insert(T.left, x);
  T.data < x : return Insert(T.right, x);
endcase
}
```

This is where call by reference makes a difference.

Advantage of reference parameter is that the call has the original pointer not a copy.

Call by Value vs Call by Reference

- Call by value
  - › Copy of parameter is used

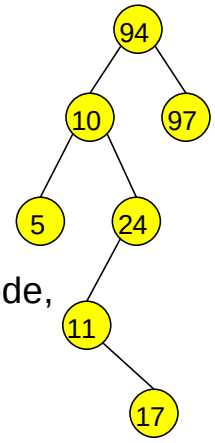


used inside call of F

- Call by reference
  - › Actual parameter is used

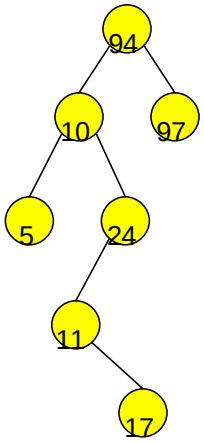
Delete Operation

- Delete is a bit trickier…Why?
- Suppose you want to delete 10
- Strategy:
  - › Find 10
  - › Delete the node containing 10
- Problem: When you delete a node, what do you replace it by?



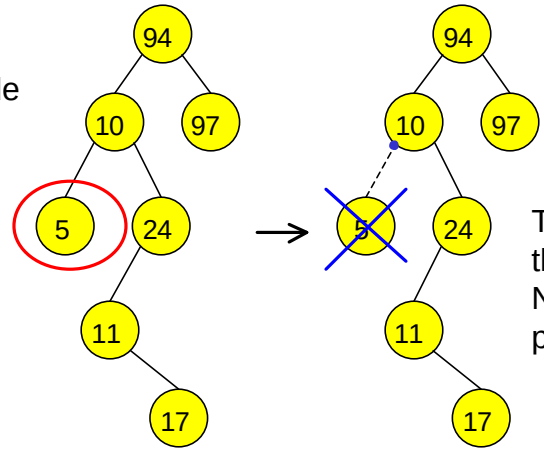
Delete Operation

- Problem: When you delete a node, what do you replace it by?
- Solution:
  - › If it has no children, by NULL
  - › If it has 1 child, by that child
  - › If it has 2 children, by the node with the smallest value in its right subtree (the successor of the node)



Delete “5” - No children

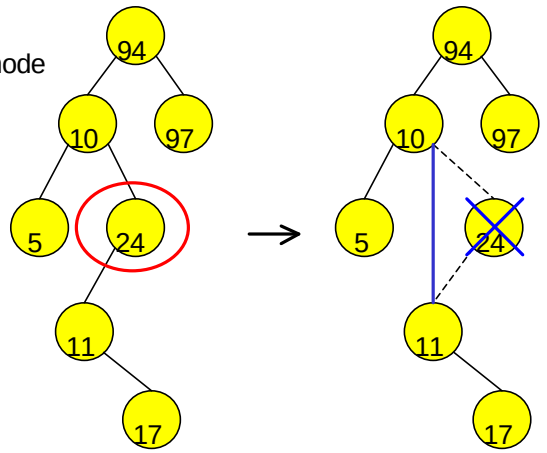
Find 5 node



Then Free the 5 node and NULL the pointer to it

Delete “24” - One child

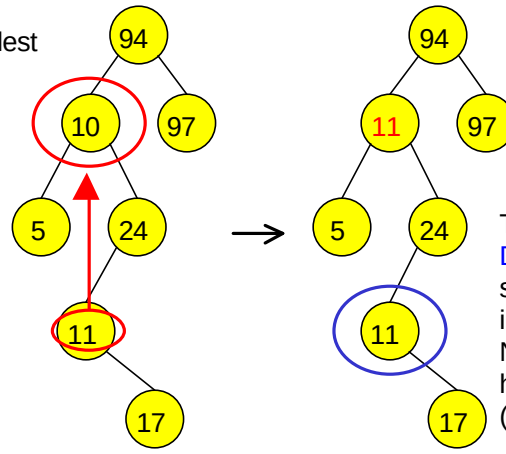
Find 24 node



Then Free the 24 node and replace the pointer to it with a pointer to its child

Delete “10” - two children

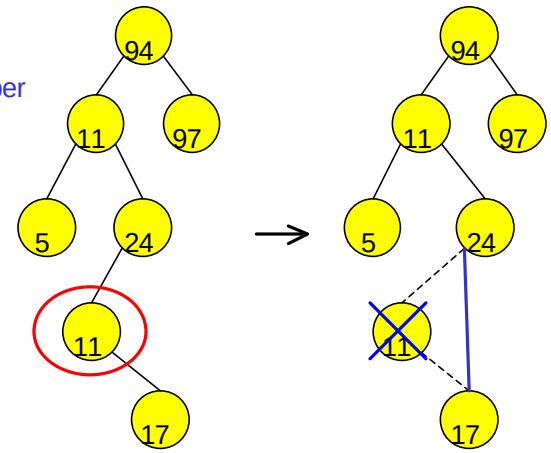
Find 10,
Copy the smallest value in right subtree into the node



Then (recursively) Delete node with smallest value in right subtree
Note: it cannot have two children (why?)

Then Delete “11” - One child

Remember 11 node



Then Free the 11 node and replace the pointer to it with a pointer to its child

Remove from Text

```
private BinaryNode remove( Comparable x, BinaryNode t) {
if ( t == null) return t;                          // not found
if ( x.compareTo( t.element ) < 0 )
    t.left = remove( x, t.left );                  // search left
else if ( x.compareTo( t.element) > 0 )
    t.right = remove(x, t.right );                 // search right
else if  (t.left != null && t.right != null)       // found it; two children
    {   t.element = findMin (t.right ).element;    // find the min, replace,
        t.right = remove( t.element, t.right);  }     and remove it
else t = (t.left != null ) ? t.left : t.right;     // found it; one child
return t;   }
```

FindMin Solution

```
FindMin(T : tree pointer) : tree pointer {
// precondition: T is not null //
if T.left = null return T
else return FindMin(T.left)
}
```

Note: Look at the “remove” method in the book.
