Find	$O(N)$	$O(\log N)$	$O(N)$	$O(\log N)$	$O(\log N)$
Delete	$O(N)$	$O(N)$	$O(N)$	$O(\log N)$	$O(\log N)$

Hash Tables

- Find, insert, delete: constant time on average!
- A **hash table** is an array of some fixed size.
- General idea:

Hash Tables

Key space of size M , but we only want to store subset of size N , where $N \ll M$.

- Keys are identifiers in programs. Compiler keeps track of them in a symbol table.
- Keys are student names. We want to look up student records quickly by name.
- Keys are chess configurations in a chess playing program.
- Keys are URLs in a database of web pages.

Simple Integer Hash Functions

- key space = integers
- TableSize = 10
- $h(K) = ?$

- Multiple objects in a cell called a collision

String Hash Functions?

key space = strings

$K = s_0 s_1 s_2 \dots s_{m-1}$ (where s_i are chars: $s_i \in [0, 128]$)

What are some desirable properties for a hash function?

Some String Hash Functions

key space = strings

$K = s_0 s_1 s_2 \dots s_{m-1}$ (where s_i are chars: $s_i \in [0, 128]$)

1. $h(K) = s_0 \% \text{TableSize}$

2. $h(K) = \left(\sum_{i=0}^{m-1} s_i \% \right) \text{TableSize}$

3. $h(K) = \left(\sum_{i=0}^{k-1} s_i \cdot 37^i \% \right) \text{TableSize}$

4. $h(K) = \left(\sum_{i=0}^{m-1} s_i \cdot 128^i \% \right) \text{TableSize}$

Collision Resolution

Collision:

when two keys map to the same location in the hash table.

How can we cope with collisions?

Separate Chaining

Insert:

Thoughts about this?

Our goal is to keep it such that a simple list is good enough

Separate chaining: All keys that map to the same hash value are kept in a list (or “bucket”).

Analysis of Separate Chaining

The **load factor**, λ , of a hash table is

$$\lambda = \frac{N \leftarrow \text{no. of elements}}{\text{TableSize}}$$

Separate chaining: λ = average # of elems per bucket

Average cost of:

- Unsuccessful find?
- Successful find?
- Insert?

Analysis of Separate Chaining

The **load factor**, λ , of a hash table is

$$\lambda = \frac{N \leftarrow \text{no. of elements}}{\text{TableSize}}$$

Separate chaining: λ = average # of elems per bucket

Average cost of:

– Unsuccessful find? λ

– Successful find? $\lambda / 2$

– Insert? λ

(assuming you check the item is not already there)
