

CSE 373: Heaps (other operations and variations)

Chapter 6

Heaps: Quick Recap

Heaps:

- structure is a complete binary tree
- each node must be smaller than its descendants

- main operations are **insert()** and **deleteMin()**
- heaps have a compact array-based representation

Other Operations: decreaseKey()

decreaseKey() – lowers a node's value
(while preserving heap ordering)

`H.decreaseKey(, 6);`

UW, Autumn 1999

CSE 373 – Data Structures and Algorithms

Brad Chamberlain

decreaseKey() – Continued

running time?

UW, Autumn 1999

Brad Chamberlain

increaseKey()

increaseKey() – raises a node's value

```
H.increaseKey( 6 );
```

UW, Autumn 1999

Brad Chamberlain

delete()

delete() – removes a node from the heap

```
H.delete(6);
```

UW, Autumn 1999

CSE 373 – Data Structures and Algorithms

Brad Chamberlain

delete() – Continued

running time?

Brad Chamberlain

Let's Write a Heap Routine...

UW, Autumn 1999

CSE 373 – Data Structures and Algorithms

Brad Chamberlain

buildHeap()

buildHeap() – creates a heap from an array

| | | | | | | | | | | | |
|----|---|----|---|----|---|---|---|---|---|---|---|
| 12 | 5 | 11 | 3 | 10 | 6 | 9 | 4 | 8 | 1 | 7 | 2 |
|----|---|----|---|----|---|---|---|---|---|---|---|

Straightforward Implementation: **insert()**
elements into an empty heap one at a time

running time?

UW, Autumn 1999

CSE 373 – Data Structures and Algorithms

Brad Chamberlain

buildHeap() - Continued

Better Implementation: Treat input array as a heap and “percolate down” first $n/2$ values

running time?

UW, Autumn 1999

CSE 373 - Data Structures and Algorithms

Brad Chamberlain

buildHeap() - even more

UW, Autumn 1999

CSE 373 - Data Structures and Algorithms

Brad Chamberlain

buildHeap() running time

UW, Autumn 1999

Brad Chamberlain

MaxHeaps

MaxHeaps: the dual of the Heaps we've defined

- support fast **insert()** and **deleteMax()** ops
- work exactly the same as (Min)Heaps

Why is **deleteMax()** expensive on a normal minheap?

What's the running time?

UW, Autumn 1999

CSE 373 – Data Structures and Algorithms

Brad Chamberlain

d-Heaps

d-Heaps: Just like normal heaps but with d children rather than 2

Intuition: tree will be shallower so ops will be faster

However...

- more comparisons need to be made when percolating down
- finding parent/children may be slower

What about asymptotic running time?

Bottom Line: 4-heaps *may* outperform 2-heaps

Merging Heaps

How to merge heaps effectively?

Straightforward method: copy both arrays into a single array and use `buildHeap()`
running time?

Advanced methods:

- pointer-based imbalanced heaps
 - *leftist heaps* – a bit like AVL trees; $O(\log n)$ merge
 - *skew heaps* – like Splay trees; $O(\log n)$ amortized ops
 - *binomial queues* – $O(\log n)$ merge, but $\sim O(1)$ insert
