2

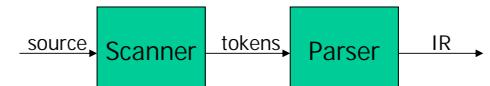

Structure of a Compiler

- First approximation
 - » Front end: analysis
 - Read source program and understand its structure and meaning
 - » Back end: synthesis
 - Generate equivalent target language program

Front End

- Split into two parts
 - » **Scanner:** Responsible for converting character stream to token stream
 - Also strips out white space, comments
 - » **Parser:** Reads token stream; generates IR
- Both of these can be generated automatically or by hand
 - » Source language specified by a formal grammar
 - » Tools read the grammar and generate scanner & parser (either table-driven or hard coded)

Lex and Yacc

7-Dec-2005

cse413-20-tools © 2005 University of Washington

5

Lex

- Lex is a lexical analyzer generator
- Lex helps write programs whose control flow is directed by instances of regular expressions in the input stream
 - » editor-script type transformations
 - » segmenting input in preparation for a parsing routine, ie, tokenizing
- You define the scanner by providing the patterns to recognize and the actions to take

7-Dec-2005

cse413-20-tools © 2005 University of Washington

6

Lex Input

```
%{  
Declarations  
%}  
Definitions  
%%  
Rules  
%%  
User Subroutines
```

- Declarations - *optional* user supplied header code
- Definitions - *optional* definitions to simplify the Rules section
- Rules - token definition patterns and associated actions in C
- User subroutines - *optional* helper functions

7-Dec-2005

cse413-20-tools © 2005 University of Washington

7

Lex Output

- Generates a scanner function written in C
 - » the file is lex.yy.c
 - » the function is yylex()
 - » yylex() implements the DFA that corresponds to the regular expressions you supplied using:
 - transition table for the DFA
 - action code invoked at the accept states

7-Dec-2005

cse413-20-tools © 2005 University of Washington

8

Lex Rules

- Lines in the rules section have the form
expression action
- expression is the pattern to recognize
 - » regular expressions defined as we have in class with extensions for convenience
- action is the action to take when the pattern is recognized
 - » arbitrary C code that becomes part of the DFA code

7-Dec-2005

cse413-20-tools © 2005 University of Washington

9

pattern definition match operators

x	the character "x"
[xy]	any character selected from the list given (in this case, x or y)
[x-z]	any character from the range given (in this case, x, y or z)
[^x]	any character but x, ie the complement of the character(s) specified.
.	any single character but newline.
x?	an optional x, ie, 0 or 1 occurrences of x
x*	0 or more instances of x.
x+	1 or more instances of x, equivalent to xx*
x{m,n}	m to n occurrences of x
^x	an x at the beginning of a line.
x\$	an x at the end of a line.
\x	an "x", even if x otherwise has some special meaning
"xy"	string "xy", even if xy would otherwise have some special meaning
x y	an x or a y.
x/y	an x but only if followed by y.
{xx}	the translation of xx from the definitions section.

7-Dec-2005

cse413-20-tools © 2005 University of Washington

10

actions

- When an expression is matched, Lex executes the corresponding action.
 - » the action is defined as one or more C statements
 - » if a section of the input is not matched by any pattern, then the default action is taken which consists of copying the input to the output

7-Dec-2005

cse413-20-tools © 2005 University of Washington

11

context for the action code

- There are several global variables defined at the point when the action code is called
 - » yytext - null terminated string containing the lexeme
 - » yyleng - the length of yytext string
 - » yylval - structured variable holding attributes of the recognized token
 - » yylloc - structured variable holding location information about the recognized token

7-Dec-2005

12

count.l - count chars, words, lines

```
%{  
    int numchar = 0, numword = 0, numline = 0;  
}  
  
%%  
  
\n        {numline++; numchar++};  
[^ \t\n]+ {numword++; numchar+= yylen;}  
.        {numchar++};  
  
%%  
  
main()  
{  
    yylex();  
    printf("%d\t%d\t%d\n", numchar, numword, numline);  
}
```

declarations

rules

user code

13

create and run count

```
create the scanner source file lex.yy.c  
[finson@walnut cse413]$ flex count.l
```

```
build the executable program count  
[finson@walnut cse413]$ gcc -o count lex.yy.c -lfl
```

```
run the program on the definition file count.l  
[finson@walnut cse413]$ ./count < count.l  
220      32      17
```

```
run the program on the generated source file lex.yy.c  
[finson@walnut cse413]$ ./count < lex.yy.c  
35824      5090      1509
```

7-Dec-2005

cse413-20-tools © 2005 University of Washington

14

histo.l - histogram of word lengths

```
int lengl[100];  
%  
[a-zA-Z]+    lengl[yylen]++;  
.|\n        ;  
%%  
yywrap() {  
    int i;  
    printf("Length  No. words\n");  
    for(i=0; i<100; i++)  
        if (lengl[i] > 0)  
            printf("%5d%10d\n", i, lengl[i]);  
    return(1);  
}
```

declarations

rules

user code

15

Create and run histo

```
create the scanner source file lex.yy.c  
[finson@walnut cse413]$ flex histo.l
```

```
build the executable program histo  
[finson@walnut cse413]$ gcc -o histo lex.yy.c -lfl
```

```
run the program on the definition file histo.l  
[finson@walnut cse413]$ ./histo < histo.l
```

Length	No. words
1	14
2	3
3	3
5	5
6	6

16

Yacc: Yet-Another Compiler Compiler

- Yacc provides a general tool for describing the input to a computer program.
 - » ie, Yacc helps write programs whose actions are directed by a language generated by some grammar
- The Yacc user specifies the structures of his input, together with code to be invoked as each such structure is recognized.
 - » Yacc turns the specification into a subroutine that handles the input process

7-Dec-2005

cse413-20-tools © 2005 University of Washington

17

Yacc Output

- Generates a parser function written in C
 - » the file is y.tab.c
 - » the function is yyparse()
 - » yyparse() implements a bottom-up, LALR(1) parser for the grammar you supplied

7-Dec-2005

cse413-20-tools © 2005 University of Washington

19

Yacc Input

```
%{  
Declarations  
%}  
Definitions  
%%  
Productions  
%%  
User Subroutines
```

- Declarations - *optional* user supplied header code
- Definitions - *optional* definitions to simplify the Rules section
- Productions - the grammar to parse and the associated actions
- User subroutines - *optional* helper functions

7-Dec-2005

cse413-20-tools © 2005 University of Washington

18

Yacc Productions

- Lines in the productions section have the form production action
- production is the grammar expression
 - » almost exactly the same as the productions we have defined in class
- action is the action to take when the pattern is recognized
 - » arbitrary C code that becomes part of the DFA code

7-Dec-2005

cse413-20-tools © 2005 University of Washington

20

example productions

```
parameters : parameter
            | parameters ',' parameter
            ;
parameters : T_KW_INT T_ID
            {printf("PARSED PARAMETER %s\n", $2);}
            ;
declarations : declaration
              | declarations declaration
              ;
declaration : T_KW_INT T_ID ';'
              {printf ("PARSED LOCAL VARIABLE %s\n", $2);}
              ;
```

7-Dec-2005

cse413-20-tools © 2005 University of Washington

21

Production format

- A grammar production has the form
 - » A : BODY ;
 - » A is the non-terminal
 - » BODY is a sequence of zero or more non-terminals and terminals
 - » ':' takes the place of '::=' or ' \rightarrow ' in our grammars
 - » ';' means the end of the production or set of productions

7-Dec-2005

cse413-20-tools © 2005 University of Washington

22

actions

- When a production is matched, Yacc executes the corresponding action.
 - » the action is defined as one or more C statements
 - » the statements can do anything
 - » if no action code is specified, then the default action is to return the value of the first item in right hand side of the production for use in higher level accumulations

7-Dec-2005

cse413-20-tools © 2005 University of Washington

23

context for the action code

- The value of the items in the production is available when the action code is called
- You can access the values of the parsed items with \$1, \$2, etc

```
parameter : T_KW_INT T_ID
            {printf("PARSED PARAMETER %s\n", $2);}
            ;
```

28

dp.l: lexical (part 2)

```
{whitespace}           { }
{alpha}({alpha}|{numeric}|_)* {
    yyval.stringValue = strdup(yytext);
    return T_ID;
}
{numeric}+
{
    yyval.intValue = atoi(yytext);
    return T_INT;
}
{comment}           { }
```

7-Dec-2005

cse413-20-tools © 2005 University of Washington

29

sample run of the dp parser

```
djohnson@skyo ex20 $ flex dp.l
djohnson@skyo ex20 $ bison -vdt dp.y
djohnson@skyo ex20 $ gcc -o parse lex.yy.c dp.tab.c -ll
djohnson@skyo ex20 $ ./parse < scanx.d
PARSED PARAMETER x
PARSED PARAMETER y
PARSED FUNCTION someFunction
PARSED PARAMETER x
PARSED LOCAL VARIABLE aSimpleInt
PARSED LOCAL VARIABLE a_S_I_2
PARSED LOCAL VARIABLE k
PARSED LOCAL VARIABLE z
PARSED FUNCTION main
djohnson@skyo ex20 $
```

7-Dec-2005

cse413-20-tools © 2005 University of Washington

30

Summary

- The actions can be *any* code you need
- If you ever need to build a program that parses character strings into data structures
 - » think Lex/Yacc, flex/bison, JLex/CUP, ...
- You can quickly build a solid parser with well defined tokens and grammar
 - » tokens are regular expressions
 - » grammar is standard Backus-Naur Form
