2

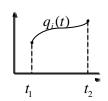

Animation

Articulated models:

- rigid parts
- connected by joints

They can be animated by specifying the joint angles (or other display parameters) as functions of time.

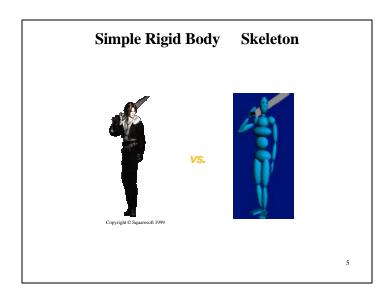

Character Representation

Character Models are rich, complex

- hair, clothes (particle systems)
- muscles, skin (FFD's etc.)

Focus is rigid-body Degrees of Freedom (DOFs)

• joint angles

Kinematics and dynamics

Kinematics: how the positions of the parts vary as a function of the joint angles.

Dynamics: how the positions of the parts vary as a function of applied forces.

6

Key-frame animation

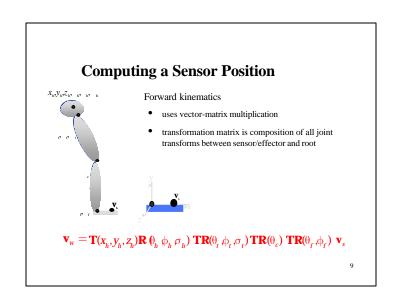

- Each joint specified at various key frames (not necessarily the same as other joints)
- System does interpolation or in-betweening

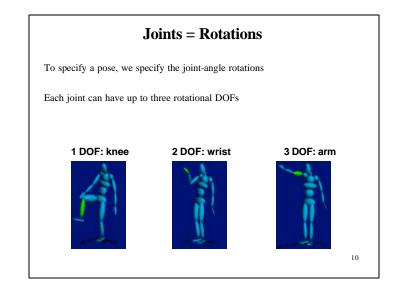

Doing this well requires:

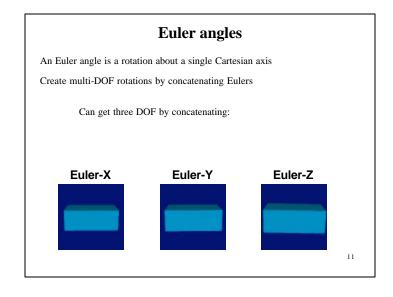

- A way of smoothly interpolating key frames: **splines**
- A good interactive system
- A lot of skill on the part of the animator

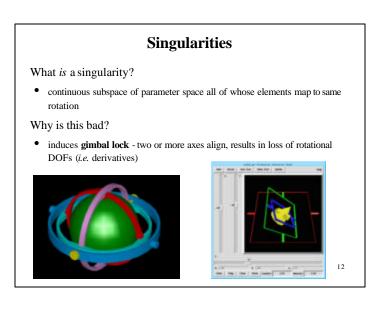

each bone relative to parent
easy to limit joint angles

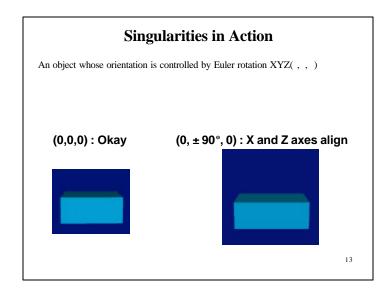

Efficient Skeleton: Hierarchy

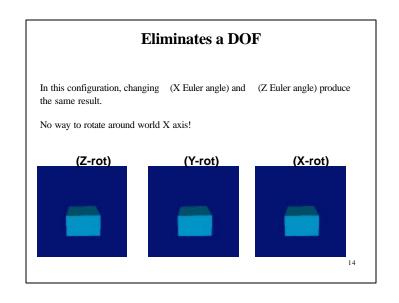

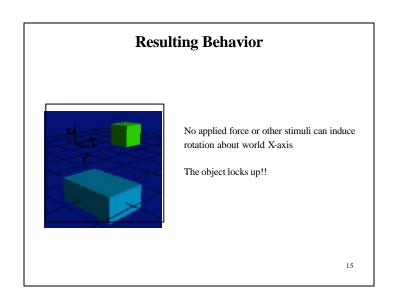

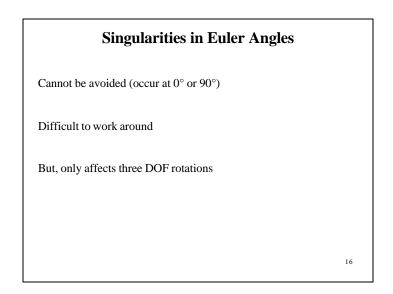

Other Properties of Euler Angles

Several important tasks are easy:

- interactive specification (sliders, etc.)
- joint limits
- Euclidean interpolation (Hermites, Beziers, etc.)
 - May be funky for tumbling bodies
 - fine for most joints

17

History of Quaternions

Invented by Sir William Rowan Hamilton in 1843

$$H = w + \mathbf{i} x + \mathbf{j} y + \mathbf{k} z$$

where $\mathbf{i}^2 = \mathbf{j}^2 = \mathbf{k}^2 = \mathbf{i} \mathbf{j} \mathbf{k} = -1$

I still must assert that this discovery appears to me to be as important for the middle of the nineteenth century as the discovery of fluxions [the calculus] was for the close of the seventeenth.

Hamilton

 $[quaternions] \dots although \ beautifully \ ingenious, \ have \ been \ an \ unmixed \ evil \ to \ those \ who \ have \ touched \ them \ in \ any \ way.$

Thompson

19

Quaternions

But... singularities are unacceptable for IK, optimization

Traditional solution: Use unit quaternions to represent rotations

• S³ has same topology as rotation space (a sphere), so no singularities

18

Quaternion as a 4 vector

$$\mathbf{q} = \begin{pmatrix} w \\ x \\ y \\ z \end{pmatrix} = \begin{pmatrix} w \\ \mathbf{v} \end{pmatrix}$$

Axis-angle rotation as a quaternion

$$\mathbf{q} = \begin{pmatrix} w \\ x \\ y \\ z \end{pmatrix} = \begin{pmatrix} w \\ \mathbf{v} \end{pmatrix}$$

$$\mathbf{q} = \begin{pmatrix} \cos(\mathbf{q}/2) \\ \sin(\mathbf{q}/2) \mathbf{r} \end{pmatrix}$$

21

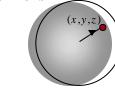

Quaternion Product

$$\begin{pmatrix} w_1 \\ \mathbf{v}_1 \end{pmatrix} \begin{pmatrix} w_2 \\ \mathbf{v}_2 \end{pmatrix} = \begin{pmatrix} w_1 w_2 - \mathbf{v}_1 \cdot \mathbf{v}_2 \\ w_1 \mathbf{v}_2 + w_2 \mathbf{v}_1 + \mathbf{v}_1 \times \mathbf{v}_2 \end{pmatrix}$$

$$\begin{pmatrix} w_1 \\ \mathbf{v}_1 \end{pmatrix} \begin{pmatrix} w_2 \\ \mathbf{v}_2 \end{pmatrix} \neq \begin{pmatrix} w_2 \\ \mathbf{v}_2 \end{pmatrix} \begin{pmatrix} w_1 \\ \mathbf{v}_1 \end{pmatrix}$$

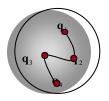

23

$$|\mathbf{q}| = 1$$

 $x^2 + y^2 + z^2 + w^2 = 1$

22

Quaternion Conjugate

$$\mathbf{q}^* = \begin{pmatrix} w_1 \\ \mathbf{v}_1 \end{pmatrix} = \begin{pmatrix} w_1 \\ -\mathbf{v}_1 \end{pmatrix}$$

$$(\mathbf{p}^*)^* = \mathbf{p}$$

$$(\mathbf{pq})^* = \mathbf{q}^* \mathbf{p}^*$$

$$(\mathbf{p}+\mathbf{q})^* = \mathbf{p}^* + \mathbf{q}^*$$

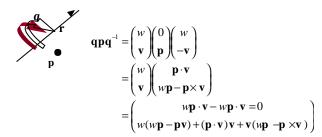

Quaternion Inverse

$$\mathbf{q}^{-1}\mathbf{q} = 1$$

$$\mathbf{q}^{-1} = \mathbf{q}^* / |\mathbf{q}| = {w \choose -\mathbf{v}} / |\mathbf{q}| = {w \choose -\mathbf{v}} / (w^2 + \mathbf{v} \cdot \mathbf{v})$$

25

Quaternion Rotation

What about a quaternion product q, q,?

26

Quaternion constraints

Restricting the rotation cone

$$\frac{1 - \cos(\boldsymbol{q}_x)}{2} = q_y^2 + q_z^2$$

Restricting the rotation twist around an axis

$$\tan(\mathbf{q}/2) = \frac{q_{axis}}{a}$$

27

Matrix Form

$$\mathbf{q} = \begin{pmatrix} w \\ x \\ y \\ z \end{pmatrix}$$

$$\mathbf{M} = \begin{pmatrix} 1 - 2y^2 - 2z^2 & 2xy + 2wz & 2xz - 2wy \\ 2xy - 2wz & 1 - 2x^2 - 2z^2 & 2yz + 2wx \\ 2xz + 2wy & 2yz - 2wx & 1 - 2x^2 - 2y^2 \end{pmatrix}$$

Quaternions: What Works

Simple formulae for converting to rotation matrix

Continuous derivatives - no singularities

"Optimal" interpolation - geodesics map to shortest paths in rotation space

Nice calculus (corresponds to rotations)

29

What Hierarchies Can and Can't Do

Advantages:

- Reasonable control knobs
- · Maintains structural constraints

Disadvantages:

- Doesn't always give the "right" control knobs
 - e.g. hand or foot position re-rooting may help
- Can't do closed kinematic chains (keep hand on hip)
- · Other constraints: do not walk through walls

30

Procedural Animation

Transformation parameters as functions of other variables

Simple example:

- a clock with second, minute and hour hands
- · hands should rotate together
- express all the motions in terms of a "seconds" variable
- whole clock is animated by varying the seconds parameter

31

Models as Code: draw-a-bug

```
void draw_bug(walk_phase_angle, xpos, ypos zpos){
 pushmatrix
 translate(xpos,ypos,zpos)
 calculate all six sets of leg angles based on
   walk phase angle.
 draw bug body
 for each leg:
   pushmatrix
   translate(leg pos relative to body)
   draw_bug_leg(thetal&theta2 for that leg)
   popmatrix
 popmatrix
void draw_bug_leg(float theta1, float theta2){
 glPushMatrix();
 glRotatef(theta1,0,0,1);
 draw_leg_segment(SEGMENT1_LENGTH)
 glTranslatef(SEGMENT1_LENGTH,0,0);
 glRotatef(theta2,0,0,1);
 draw_leg_segment(SEGMENT2_LENGTH)
 glPopMatrix();
                                                          32
```

Hard Example

In the figure below, what expression would you use to calculate the arm's rotation angle to keep the tip on the star-shaped wheel as the wheel rotates???
