Affine transformations

Brian Curless CSE 457 Spring 2013

Geometric transformations

Geometric transformations will map points in one space to points in another: (x', y', z') = f(x, y, z).

These transformations can be very simple, such as scaling each coordinate, or complex, such as non-linear twists and bends.

We'll focus on transformations that can be represented easily with matrix operations.

Vector representation

We can represent a **point**, $\mathbf{p} = (x,y)$, in the plane or $\mathbf{p} = (x,y,z)$ in 3D space

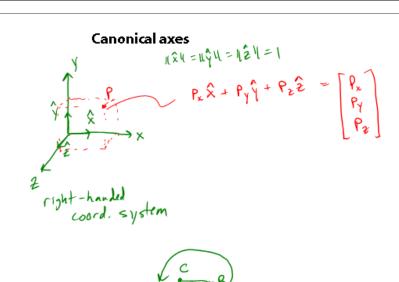

as column vectors

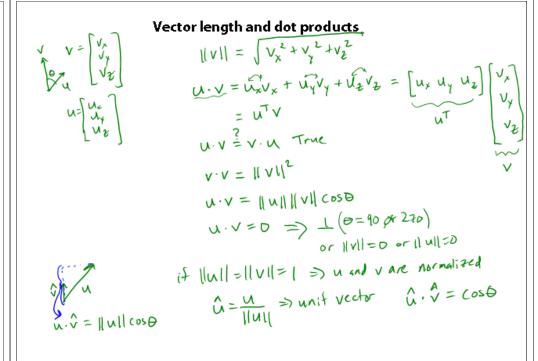

$$\begin{bmatrix} x \\ y \end{bmatrix} \quad \begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

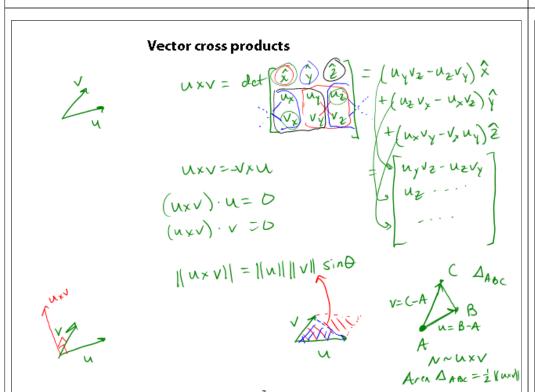

• as row vectors $\begin{bmatrix} x & y \end{bmatrix}$

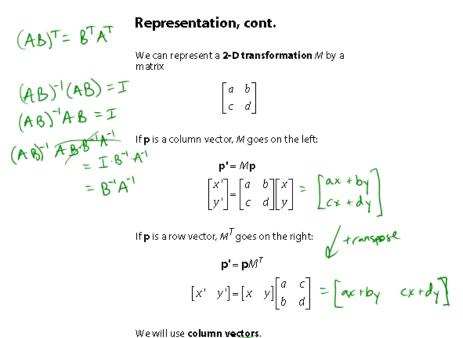

$$[x \ y \ z]$$

3

Two-dimensional transformations

Here's all you get with a 2×2 transformation matrix M:

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

So:

$$x' = ax + by$$
$$y' = cx + dy$$

We will develop some intimacy with the elements $a,b,c,d\dots$

9

Identity

Suppose we choose a=d=1, b=c=0:

• Gives the identity matrix:

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

• Doesn't move the points at all

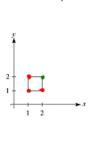

10

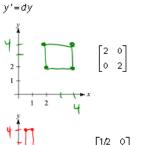

Scaling

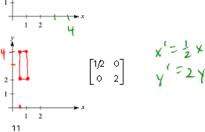

Suppose we set b=c=0, but let a and d take on any positive value:

• Gives a scaling matrix:

Provides differential (non-uniform) scaling in x andy:
 x' = ax

Reflection

Suppose we keep b=c=0, but let either a or d gonegative.

Examples:

$$\begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix} \begin{array}{c} x' = x \\ y' = y \end{array} \qquad \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{array}{c} x' = x \\ y' = -y \end{array}$$

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{array}{c} x' = x \\ y' = -y \end{array}$$

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{array}{c} x' = x \\ y' = -y \end{array}$$

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{array}{c} x' = x \\ y' = -y \end{array}$$

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{array}{c} x' = x \\ y' = -y \end{array}$$

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{array}{c} x' = x \\ y' = -y \end{array}$$

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{array}{c} x' = x \\ y' = -y \end{array}$$

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{array}{c} x' = x \\ y' = -y \end{array}$$

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{array}{c} x' = x \\ y' = -y \end{array}$$

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{array}{c} x' = x \\ y' = -y \end{array}$$

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{array}{c} x' = x \\ y' = -y \end{array}$$

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{array}{c} x' = x \\ y' = -y \end{array}$$

12

Shear

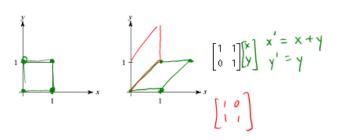

Now let's leave a=d=1 and experiment with b....

The matrix

$$\begin{bmatrix} 1 & b \\ 0 & 1 \end{bmatrix}$$

gives:

$$x' = x + by$$
$$y' = y$$

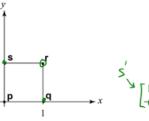

13

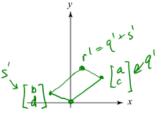

Effect on unit square

Let's see how a general 2×2 transformation M affects the unit square:

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} [\mathbf{p} \quad \mathbf{q} \quad \mathbf{r} \quad \mathbf{s}] = \begin{bmatrix} \mathbf{p'} \quad \mathbf{q'} \quad \mathbf{r'} \quad \mathbf{s'} \end{bmatrix}$$

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} 0 & 1 & 1 & 0 \\ 0 & 0 & 1 & 1 \end{bmatrix} = \begin{bmatrix} 0 & a & b + b \\ 0 & c & c + d \\ 0 & c & c + d \end{bmatrix} \begin{bmatrix} b \\ d \\ 0 & c \end{bmatrix}$$

14

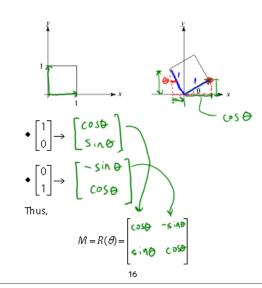

Effect on unit square, cont.

Observe:

- Origin invariant under M
- M can be determined just by knowing how the corners (1,0) and (0,1) are mapped
- a and d give x- and y-scaling
- bandcgivex-andy-shearing

Rotation

From our observations of the effect on the unit square, it should be easy to write down a matrix for "rotation about the origin":

Limitations of the 2 x 2 matrix

A 2 x 2 linear transformation matrix allows

- Scaling
- Rotation
- Reflection
- Shearing

Q: What important operation does that leave out?

17

Homogeneous coordinates

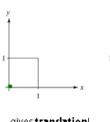

We can loft the problem up into 3-space, adding a third component to every point:

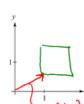

$$\begin{bmatrix} x \\ y \end{bmatrix} \rightarrow \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} \checkmark$$

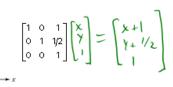

Adding the third "w" component puts us in homogenous coordinates.

Then, transform with a 3 x 3 matrix:

$$\begin{bmatrix} x' \\ y' \\ w' \end{bmatrix} = \mathcal{T}(\mathbf{t}) \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & t_x \\ 0 & 1 & t_y \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = \begin{bmatrix} x + t_y \\ y + t_y \\ 1 \end{bmatrix}$$

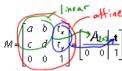

...gives translation!

Affine transformations

The addition of translation to linear transformations gives us affine transformations.

In matrix form, 2D affine transformations always look

2D affine transformations always have a bottom row of [0 0 1].

An "affine point" is a "linear point" with an added wcoordinate which is always 1:

$$\mathbf{p}_{\mathsf{aff}} = \begin{bmatrix} \mathbf{p}_{\mathsf{lin}} \\ 1 \end{bmatrix} = \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$$

MPAH = [A t Pin]

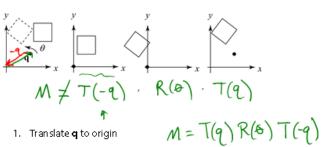

Applying an affine transformation gives another affine point:

$$\mathcal{M} \mathbf{p}_{\text{aff}} = \begin{bmatrix} \mathcal{A} \mathbf{p}_{\text{lin}} + \mathbf{t} \\ 1 \end{bmatrix}$$

Rotation about arbitrary points

Until now, we have only considered rotation about the origin.

With homogeneous coordinates, you can specify a rotation, θ about any point $\mathbf{q} = [\mathbf{q}_{\mathbf{y}} \mathbf{q}_{\mathbf{y}} \mathbf{1}]^{\mathsf{T}}$ with a matrix:

- 1. Translate **q** to origin

- 2. Rotate
- 3. Translate back

Note: Transformation order is important!!

Points and vectors

Vectors have an additional coordinate of w=0. Thus, a change of origin has no effect on vectors.

Q: What happens if we multiply a vector by an affine

$$Mv = \begin{bmatrix} a & b & tx \\ c & d & ty \\ o & o & 1 \end{bmatrix} \begin{bmatrix} v_x \\ v_y \\ b \end{bmatrix} = \begin{bmatrix} av_x + bv_y \\ cv_x + dv_y \\ 0 \end{bmatrix}$$

These representations reflect some of the rules of affine operations on points and vectors:

point+vector
$$\rightarrow$$
 point+point \rightarrow chaos

$$p(t) = p_0 + tu$$

One useful combination of affine operations is:

$$p(t) = p_0 + tu$$

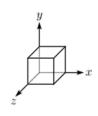

Basic 3-D transformations: scaling

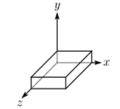

Some of the 3-D affine transformations are just like the 2-D ones.

In this case, the bottom row is always [0 0 0 1].

For example, scaling:

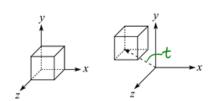

$$\begin{bmatrix} x' \\ y' \\ z' \\ 1 \end{bmatrix} = \begin{bmatrix} s_x & 0 & 0 & 0 \\ 0 & s_y & 0 & 0 \\ 0 & 0 & s_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

Translation in 3D

$$\begin{bmatrix} x' \\ y' \\ z' \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & t_x \\ 0 & 1 & 0 & t_y \\ 0 & 0 & 1 & t_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix}$$

Rotation in 3D

Rotation now has more possibilities in 3D:

$$R_{\chi}(\alpha) = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos \alpha & -\sin \alpha & 0 \\ 0 & \sin \alpha & \cos \alpha & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$R_{\chi}(\beta) = \begin{bmatrix} \cos \beta & 0 & \sin \beta & 0 \\ 0 & 1 & 0 & 0 \\ -\sin \beta & 0 & \cos \beta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$R_{\chi}(\gamma) = \begin{bmatrix} \cos \gamma & -\sin \gamma & 0 & 0 \\ \sin \gamma & \cos \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$
Use right hand rule

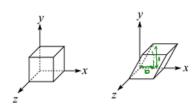

A general rotation can be specified in terms of a produut of these three matrices. How else might you specify a rotation?

Shearing in 3D

Shearing is also more complicated. Here is one example:

We call this a shear with respect to the x-z plane.

Properties of affine transformations

Here are some useful properties of affine transformations:

- Lines map to lines
- · Parallel lines remain parallel
- Midpoints map to midpoints (in fact, ratios are always preserved)

ratio =
$$\frac{\|\mathbf{p}\mathbf{q}\|}{\|\mathbf{q}\mathbf{r}\|} = \frac{s}{t} = \frac{\|\mathbf{p}'\mathbf{q}'\|}{\|\mathbf{q}'\mathbf{r}'\|}$$

Affine transformations in OpenGL

Open GL maintains a "modelview" matrix that holds the current transformation M.

The modelview matrix is applied to points (usually vertices of polygons) before drawing.

It is modified by commands including:

- glLoadIdentity() $M \leftarrow I$ - set M to identity
- + glTranslatef(t_x , t_y , t_z) $M \leftarrow MT$ - translate by (t₂, t₃, t₂)
- glRotatef(θ, x, y, z) $M \leftarrow MR$ - rotate by angle about axis (x, y, z)
- glScalef(s_s, s_v, s_t) $M \leftarrow MS$ - scale by (s_x, s_y, s_z)

Note that OpenGL adds transformations by postmultiplication of the modelview matrix.

Summary

What to take away from this lecture:

- All the names in boldface.
- How points and transformations are represented.
- · How to compute lengths, dot products, and cross products of vectors, and what their geometrical meanings are.
- What all the elements of a 2 x 2 transformation matrix do and how these generalize to 3 x 3 transformations.
- · What homogeneous coordinates are and how they work for affine transformations.
- How to concatenate transformations.
- The mathematical properties of affine transformations.
