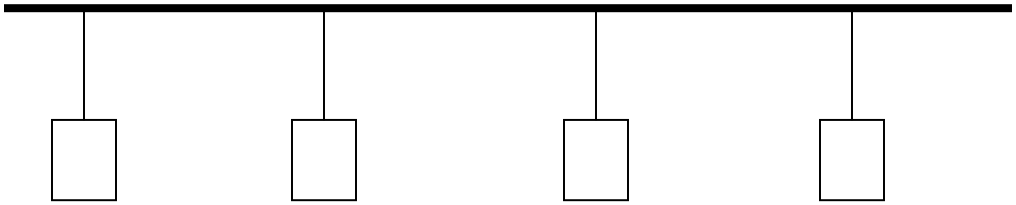
CSE 461: Introduction to Computer Communications Networks
Winter 2009

Module 3
Direct Link Networks
Enet Summary / 802.11

John Zahorjan
zahorjan@cs.washington.edu
534 Allen Center

Ethernet / 802.3



(This shows the original, 3Mbps Ethernet. Modern versions typically look different at the physical level.)

- CSMA/CD
  - MA → multiple access
  - CS → carrier sense
  - CD → collision detect

Error Handling

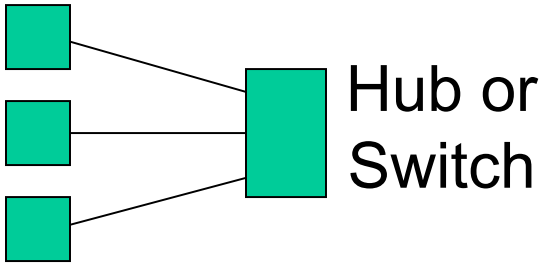
- Highly reliable delivery in the absence of collisions
  $\rightarrow$ overhead of FEC/ARQ not justified in these cases
- Loss is certain when there is a collision
  $\rightarrow$ CD allows ARQ on collisions
- Potential for collision collapse
  - Collisions tend to synchronize re-transmission attempts
  - As collision resolution takes longer and longer, more and more nodes have something to send $\rightarrow$ more collisions
- Solution: randomize retransmission attempts

Binary Exponential Backoff

- If you've experienced k consecutive collisions:
  - pick a random number in [0, 2^k-1]
  - Wait that many slot times, then perform CS and send
- "Binary exponential backoff" ensures stability
  - Network never suffers collision collapse
  - Limiting network utilization is 1/e
- One way to think about collision resolution / backoff
  - Goal: want one node to decide to send in the first slot following the collision
  - Having N nodes choose slot 0 with probability 1/N is a distributed mechanism to (roughly) achieve that
  - Don't know N...

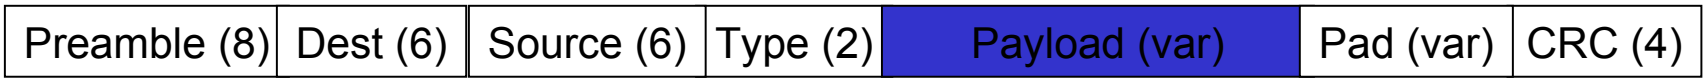
Modern Ethernet

- Modern Ethernets (100Mbps / 1Gbps / 10Gbps) look like this



- Why?

The Ethernet Frame / Addressing



- Preamble lets the receiver synch
- Addresses are 6-bytes
- Type field allows demultiplexing
  - Overloaded to be a length field in some modern variants
- Minimum payload is 46-bytes; max is 1500
  - Pad is necessary if the actual data < 46 bytes
- CRC for error detection

Ethernet (802.2) Addresses (MAC address)

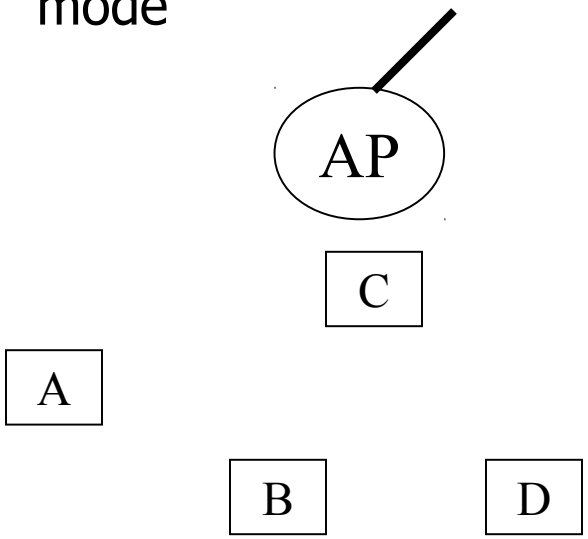
- Each interface on an Ethernet has a unique address
  - Interface cards examine each frame as it goes by
  - If the destination address matches their own address, they save the frame and notify the host
  - (Interfaces can also be put into "promiscuous mode," where they save all frames)
- Moreover, each interface in the world has a unique address
- Addresses are 48 bits ,written as sixteen hex digits
  - First 24 bits (4 million possibilities) identify a manufacturer (e.g., 3Com)
  - Last 24 bits are assigned by the manufacturer, so that all cards are unique
  - FF:FF:FF:FF:FF:FF is reserved as the broadcast address
- (Can you imagine other ways to assign addresses? Why is the one used attractive?)

Topic 2: Wireless (802.11)

ARQ

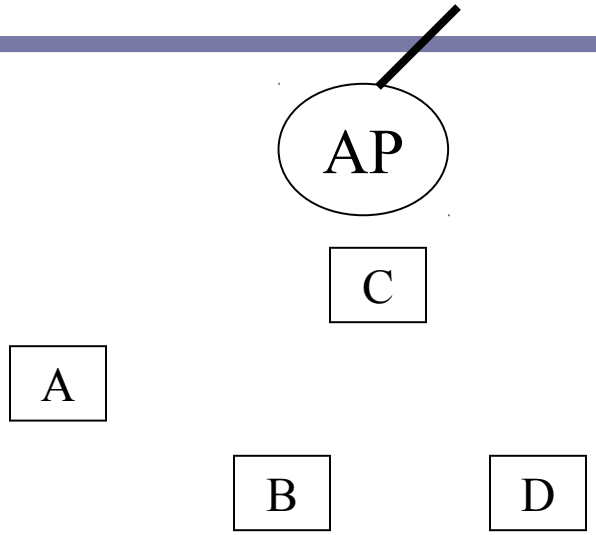
Wireless / 802.11

- There is a lot of activity in the 802.11 world…
- We'll consider here
  - 802.11b (up to 11Mbps), 802.11a (up to 54Mbps), 802.11g (up to 54Mbps) [802.11n (up to 300Mbps)]
  - Distributed Coordination Function (DCF) / infrastructure mode



- All frames to/from a host go through the AP
- AP is connected to a larger network (e.g., the Internet) and acts as a relay

802.11 Wireless Networks



- Frequency division multiplexing is used statically
  - Each AP is on a channel (e.g., 802.11b has 13 channels)
- APs (typically) broadcast their service set ids (SSIDs)
- Clients select an AP and associate with it
  - Association has a medium term lifetime – many, many frames, typically
- Access to channels is through statistical multiplexing
- How should this work?

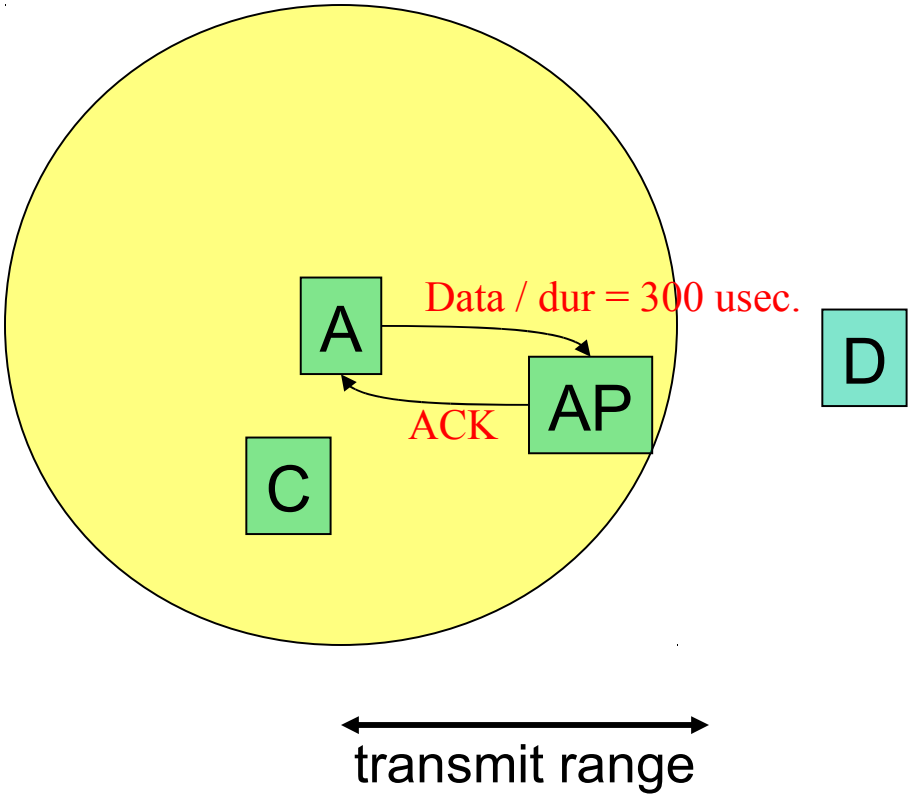
Characteristics of Wireless

- The ability of the radio to correctly decode a frame is determined by the signal-to-interference-and-noise-ratio (SINR):
  - (received signal strength) / (interference + noise) > β
  - Multiple transmit rates: higher rates are harder to decode
- The received signal strength is the transmitted strength attenuated by the materials the signal passes through, and affected by multipath/fading
  - A useful but very inaccurate model is
    - received strength = sent strength * $d^{-\alpha}$
      - α=2 for free space
      - α=3 to 4 for in-building
- Interference is the energy of other on-going transmissions. Noise is the energy generated by the receiving radio and other nearby sources (e.g., the computer's power supply).
- Connection quality between A and B may be asymmetric

Wireless Reliability

- Unlike Ethernet, frames can be lost even if only one station is transmitting
  - in fact, that's common
- 802.11 uses ARQ $\rightarrow$ explicit receiver ACKs
- ACK reliability enhanced using "reservations"
  - (data) frames contain a duration field in the header
  - The duration is the time it will take to send the current frame, plus a short idle time, plus the time to send back the ACK
  - All stations hearing the data frame are required to remain silent until the duration time has elapsed

A Picture



Basic MAC Protocol

- Carrier-sense
  - Defer if you sense a sufficiently high energy level in the air
- No collision detection
  - Transmission emanating from radio overwhelms any incoming signal
- Explicit ACKs
  - If no ACK received in reserved time
  - Use a binary exponential backoff procedure to chose a random backoff time
  - Count down that time, pausing whenever you sense a transmission in the air
  - Re-transmit when your counter reaches 0

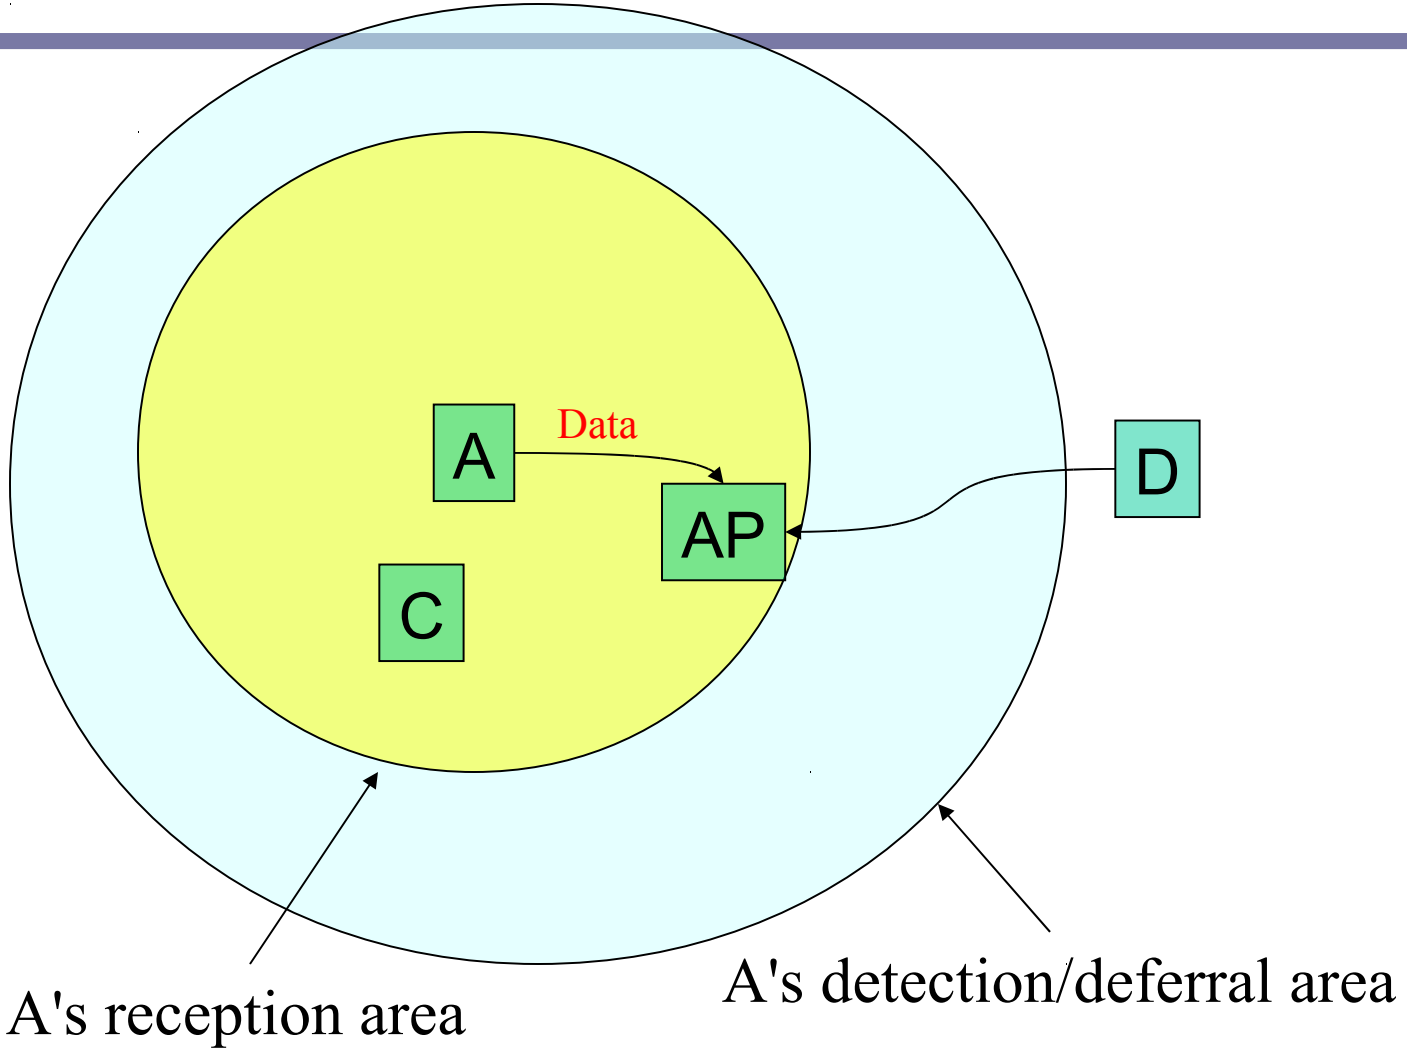
Modified ARQ

- To support this MAC level retry, the frame headers carry sequence numbers and a retry bit
  - Retry bit = 0 for first transmission of a frame, 1 for retries
  - Sequence number of each distinct frame must be distinct (until wraparound)
  - Allows receiver to detect (and throw away) duplicates
    - Same sequence number as last frame received from that source and retry bit = 1 means it's a duplicate
    - Otherwise, assume it's a new frame and deliver up to other protocol layers
- NO concept / detection of missing frames
  - Sequence numbers are used only to detect duplicates
  - "Missing" sequence numbers have no meaning
    - Successive sequence numbers to a particular destination may be any number not used too recently.

ACK Reliability

- Both the original frame and the ACK must be received or re-transmissions will take place
- As we've seen, time is reserved for the ACK, to help increase the odds it is received
- Additionally, ACKs are transmitted at the lowest rates
  - Multiple transmission rates are supported
    - E.g., 802.11b has 1, 2, 5.5, and 11Mbps
  - Slower rates have a lower SINR ratio for correct decoding

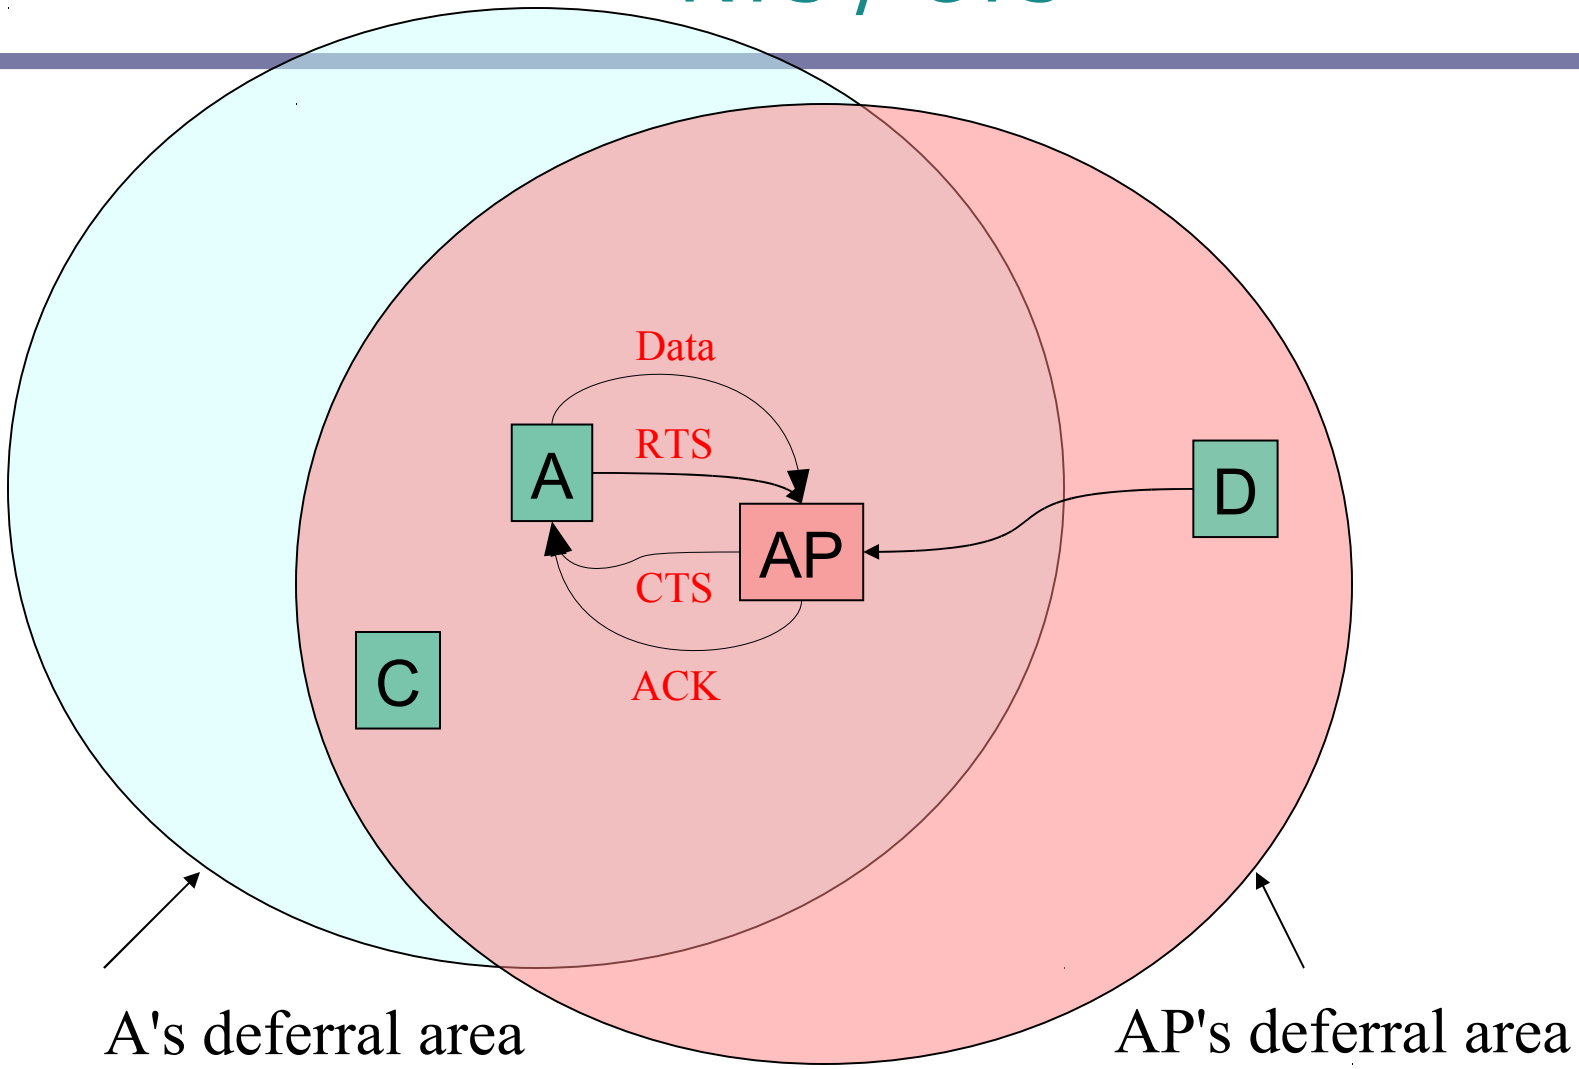
The Hidden Terminal Problem



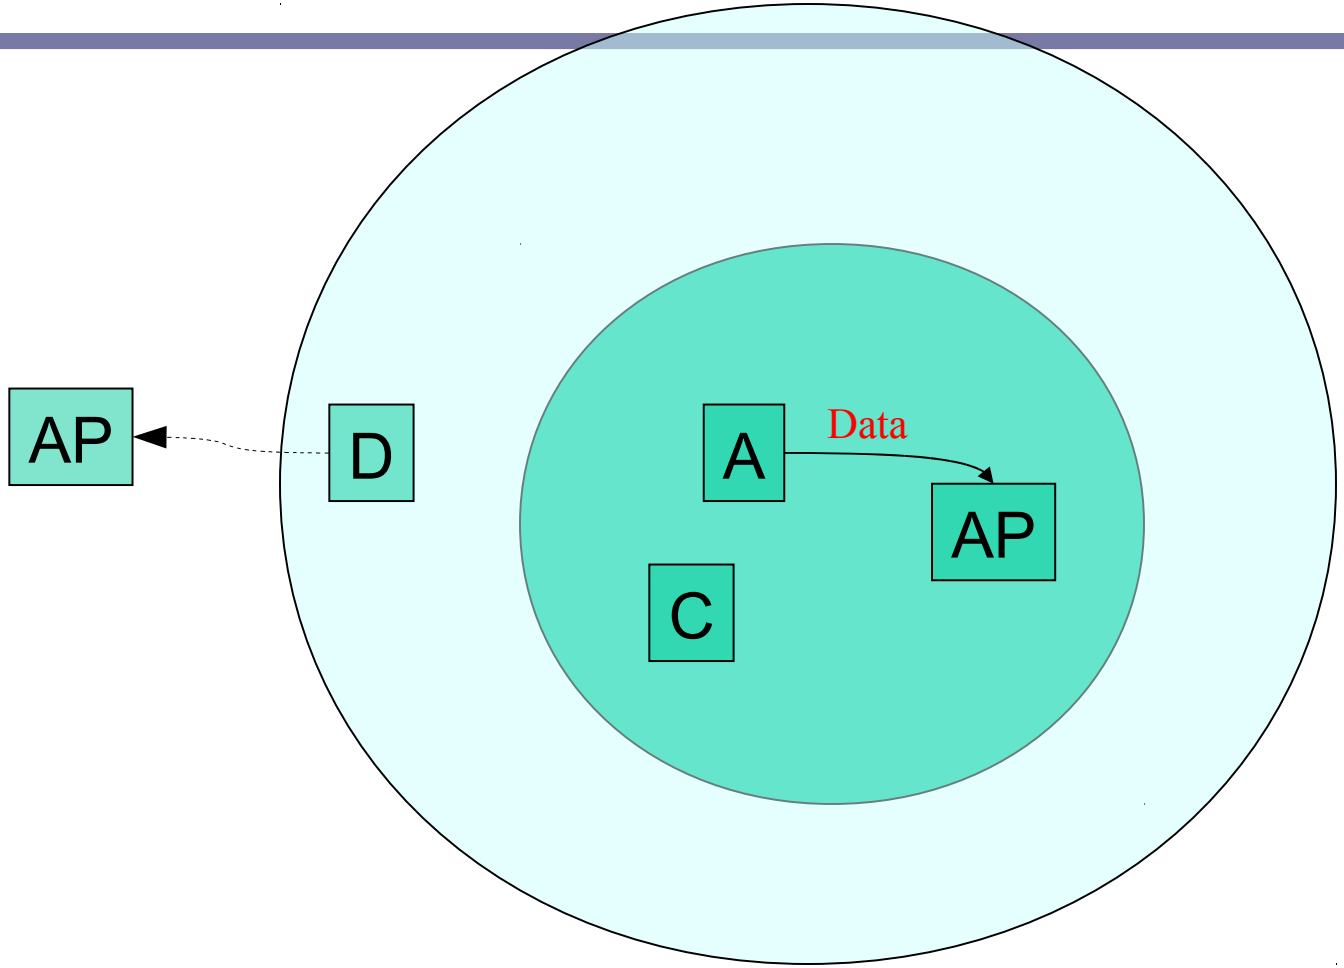
RTS / CTS

- A source may precede a data/ACK exchange with a request-to-send/clear-to-send (RTS/CTS) exchange
- The RTS carries a duration sufficient to cover the 4 frame exchange
  - With luck, it's heard by all other stations within range of the source
- The receiver responds with a CTS carrying the time required to cover the CTS / data / ACK
  - With luck, it's heard by all stations within range of the receiver
- If the CTS comes back, the source sends the data, in the normal way
- The specification does not dictate when to use RTS/CTS
  - It's actually much less used than the book implies
  - typically, there is a large, static frame size threshold, with RTS/CTS always used for frames larger than the threshold and never for those below

RTS / CTS



The Exposed Terminal Problem



Addressing

- 802.2 (48-bit) addresses are used
  - They're assigned just like with Ethernet – 24 bits name manufacturer, then 24 bits assigned by the manufacturer to that card
- Up to four addresses are contained in the header
  - Source: the address of where the frame originated
  - Transmitter: the address of the station actually transmitting
    - E.g., the AP might be forwarding a frame
  - Destination: address of the ultimate destination
  - Target: address of station that should take the frame off the air (e.g., the AP)

Frame Format

- Frames begin with a special bit pattern, sent at a low rate
- A zealous attempt has been made to keep frames as small as possible, leading to many frame types
- Here is a general idea of what they look like, though:

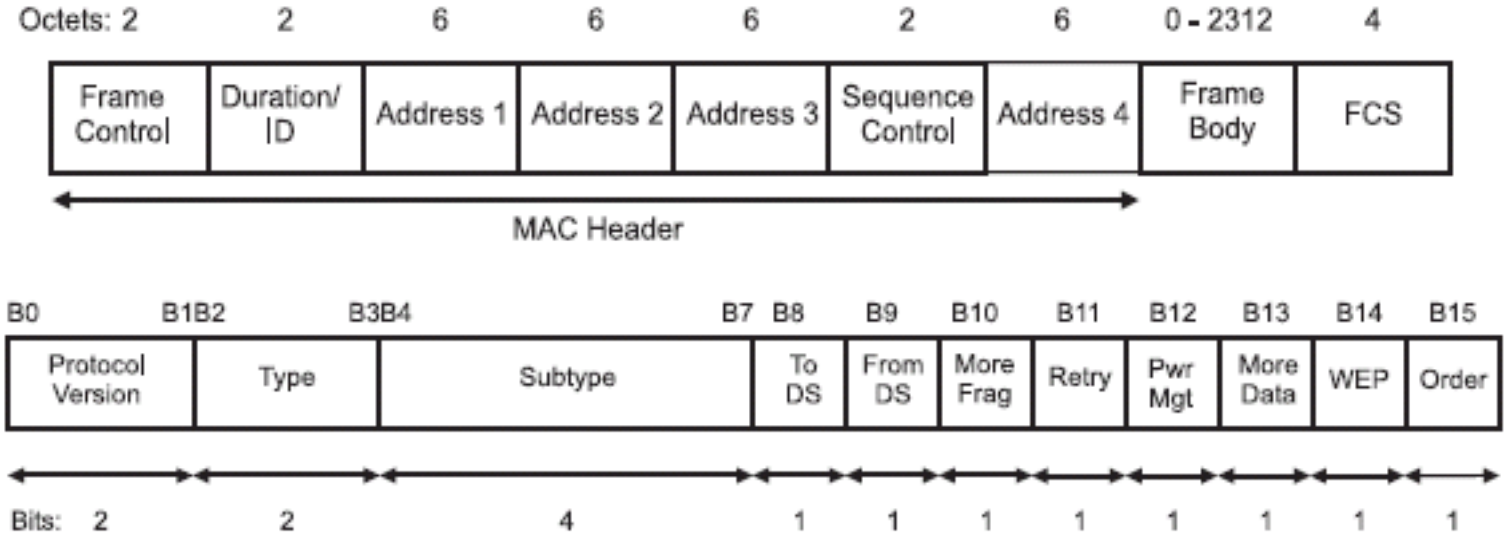


Figure 13—Frame Control field

Other Considerations

- There is an *ad hoc* mode, allowing stations to talk directly to each other (without the concept of an AP)
- The spec defines a *contention free* infrastructure (AP) mode in which the AP basically polls the clients for data
  - *This has perhaps never been implemented in any commodity hardware*
- There is support for *power management*
  - Clients may turn off their radios for a while
  - When they come back on, there are frame exchanges defined for them to ask for any frames the AP may be buffering for delivery

Summary

- Let's review the decisions made by Ethernet and 802.11:
  - Policy for acquiring in the medium
    - Ethernet: multiple access
    - 802.11: multiple access
  - How much effort to put into reliability
    - Ethernet: collision detect/ARQ; error detection/no ARQ
    - 802.11: error detection; ARQ (stop-and-wait)
  - To define an addressing scheme
    - Ethernet: source/dest 802.2 addresses
    - 802.11: 1-4 802.2 addresses
  - To define a frame format
    - Ethernet: max length (~1500 bytes); min length
    - 802.11: max length (~1500 bytes); many frame types/options (control and data frames)

A Quick Look At Alternatives

- Policy for acquiring in the medium
  - TDMA: wait your turn to send
    - Rings: a distinguished frame ("token") is required before sending is allowed
    - Token is continuously circulated among all nodes
- How much effort to put into reliability
  - No error detection
  - Error correction ("forward error correction" (FEC))
  - Sliding-window?
- To define an addressing scheme
  - Hierarchical numeric addresses (rather than flat)?
  - Properties rather than addresses ("Canon iP6200 printer")?
- To define a frame format
  - Larger frames?
  - Control frames / no control frames?
