Address Allocation and Discovery

The yellow node boots. It has a MAC address.

- It needs an IP address.
- It needs to know to use router R3.
- R3 needs to discover the new host's MAC address.

DHCP is used.

ARP is used.

Topic 1: Obtaining an IP address

- Old fashioned way: sysadmin configured each machine
 - E.g., a local file contained the IP address to use
 - Imagine deploying 50 new machines in one of the labs...
- Future fashioned way (IPV6): Stateless Autoconfiguration
 - Addresses are wide / plentiful
 - Form IPv6 address by concatenating “network’s address” (prefix) with your own MAC address
 - Learn “network address” portion from router
- Current (IPv4) way: Dynamic Host Configuration Protocol (DHCP)
 - Addresses are narrow (32-bits) / scarce
 - Have to hand them out carefully
 - Use a DHCP server that provides bootstrap info to hosts
 - Host’s IP address, gateway address, ...
 - An immediate problem: how does a host without an IP address communicate with the DHCP server?

The DHCP Problem

Host

DHCP Server

- The host doesn't have an IP address
- The host doesn't know the address of the DHCP server
- The host wants to contact the DHCP server
- We want to use IP packets to talk with the server
 - Why? Why not talk using link layer packets?

Solution: link and IP layer broadcast

The DHCP Problem Solution

Host

<i>Ethernet</i>	Src: host's MAC address Dst: FF:FF:FF:FF:FF:FF
<i>IP</i>	Src: 00:00:00:00 Dst: FF:FF:FF:FF
<i>UDP</i>	Src port: 68 Dst port: 67
<i>DHCP</i>	RN32 Hi. Startup info please...

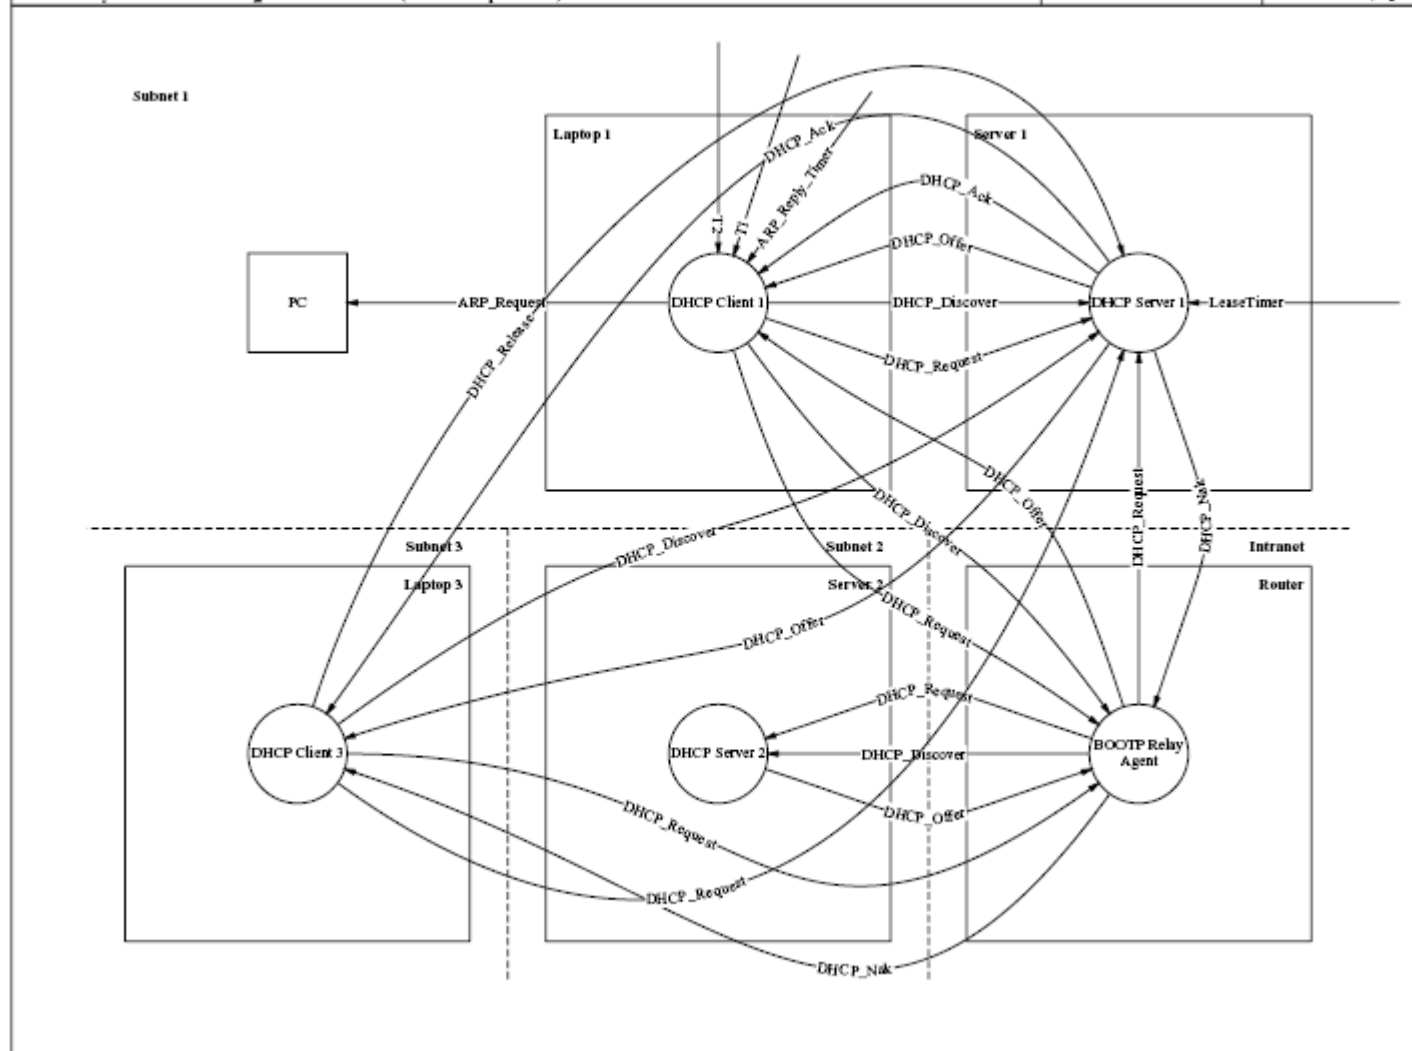

DHCP Server

<i>Ethernet</i>	Src: server's MAC address Dst: FF:FF:FF:FF:FF:FF
<i>IP</i>	Src: server's IP address Dst: FF:FF:FF:FF
<i>UDP</i>	Src port: 67 Dst port: 68
<i>DHCP</i>	RN32 Your IP is... Your gateway's IP is... ...

(As always, the actual protocol is richer than what is shown here.)

- Client is responsible for all retransmissions. (Why?)
- What dangers are there for losing IP addresses?

Topic 2: Discovering MAC's from IP's

- Host has an IP (e.g., for the gateway). It needs a MAC address to send a frame to it.
- Solution: Address Resolution Protocol (ARP)
- Exploits the physical multicast of Ethernet

The IP->MAC Problem Solution

Host

<i>Ethernet</i>	Src: host's MAC address Dst: FF:FF:FF:FF:FF:FF
<i>ARP</i>	My MAC is ... My IP is... Your MAC is...0 Your IP is...

Target host

<i>Ethernet</i>	Src: target's MAC address Dst: src's MAC address
<i>ARP</i>	My MAC is... My IP is... Your MAC is... Your IP is...

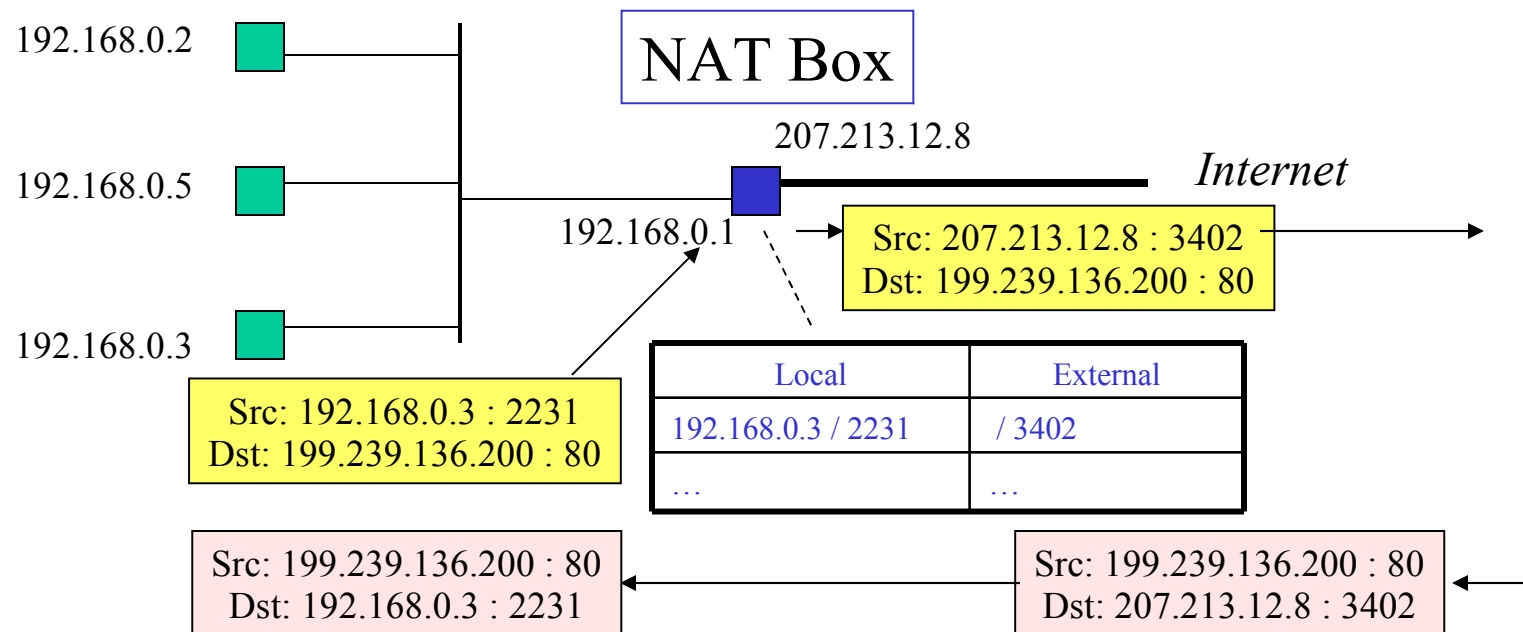

(As always, the actual protocol is richer than what is shown here.)

Topic 3: Network Address Translation (NAT)

- Turns out that there aren't all that many 32-bit strings (i.e., IP addresses)
 - The world needs more...
 - An individual network needs more...
 - You need more...
 - Your ISP will give you only one (using DHCP), but you want to connect five machines to the Internet
- NAT exploits non-routable addresses to let you build your own private network "behind the NAT box"
 - Non-routable addresses are, well, never routed
 - do not have to be globally unique (just locally unique)
- The NAT box substitutes its own IP address for outgoing packets, and the local address of the actual destination for incoming packets

NAT Overview

- Recall that IP addresses are 32-bits (e.g., 192.168.10.3)
- Recall that TCP addresses are IP addresses plus a port number
- These IP address ranges are “non-routable”:
 - 10.0.0.0 - 10.255.255.255
 - 172.16.0.0 - 172.31.255.255
 - 192.168.0.0 - 192.168.255.255

NAT and Peer-to-Peer (P2P)

- STUN (Session Traversal Utilities for NAT)
 - Heuristic designed to discover “routable” address (NAT entry) for hosts behind NATs
 - IETF RFC 5389 (<http://tools.ietf.org/html/rfc5389>)

Key Concepts

- **DHCP** provides convenient management of host startup information
- **ARP** learns the mapping from IP to MAC address
- **NAT** hides local names behind a single global name
- **STUN** permits interactions between machines behind (distinct) NATs
