CSE 527 Computational Biology

RNA: Function, Secondary Structure Prediction, Search, Discovery

The Message

Cells make lots of RNA noncoding RNA

Functionally important, functionally diverse

Structurally complex

New tools required alignment, discovery, search, scoring, etc.

RNA

DNA: DeoxyriboNucleic Acid

RNA: RiboNucleic Acid

Like DNA, except:

Lacks OH on ribose (backbone sugar)

Uracil (U) in place of thymine (T)

A, G, C as before

CH3

NH

uracil

4

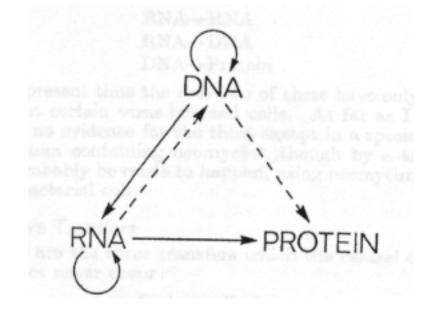

Central Dogma of Molecular Biology

FRANCIS CRICK MRC Laboratory Hills Road, Cambridge CB2 2QH

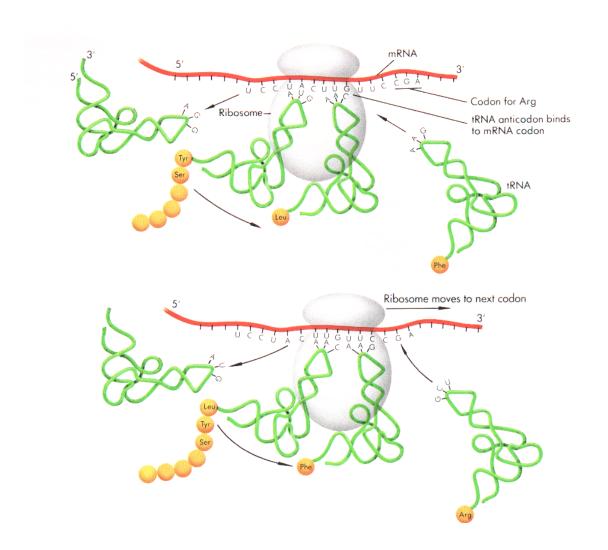

The central dogma of molecular biology deals with the detailed residue-by-residue transfer of sequential information. It states that such information cannot be transferred from protein to either protein or nucleic acid.

"The central dogma, enunciated by Crick in 1958 and the keystone of molecular biology ever since, is likely to prove a considerable over-simplification."

Fig. 2. The arrows show the situation as it seemed in 1958. Solid arrows represent probable transfers, dotted arrows possible transfers. The absent arrows (compare Fig. 1) represent the impossible transfers postulated by the central dogma. They are the three possible arrows starting from protein.

Ribosomes

Ribosomes

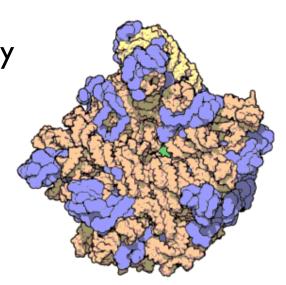

1974 Nobel prize to Romanian biologist George Palade (1912-2008) for discovery in mid 50's

50-80 proteins

3-4 RNAs (half the mass)

Catalytic core is RNA

Of course, mRNAs and tRNAs (messenger & transfer RNAs) are critical too

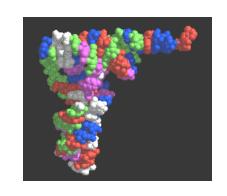

Transfer RNA

The "adapter" coupling mRNA to protein synthesis.

Discovered in the mid-1950s by Mahlon Hoagland (1921-2009,

left), Mary Stephenson, and Paul Zamecnik (1912-2009; Lasker award winner, right).

"Classical" RNAs

rRNA - ribosomal RNA (~4 kinds, 120-5k nt)

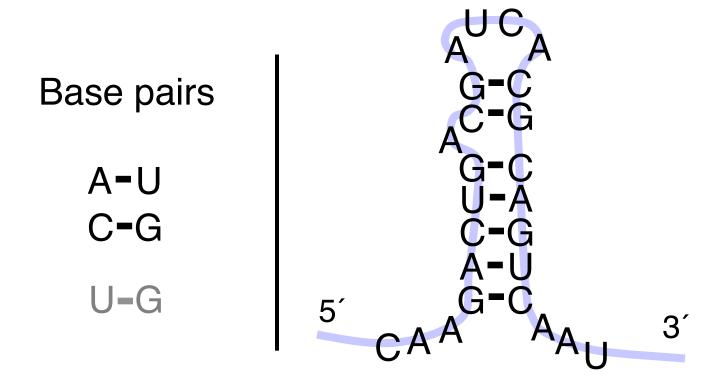

tRNA - transfer RNA (~61 kinds, ~ 75 nt)

RNaseP - tRNA processing (~300 nt)

snRNA - small nuclear RNA (splicing: UI, etc, 60-300nt)

a handful of others

RNA Secondary Structure: RNA makes helices too

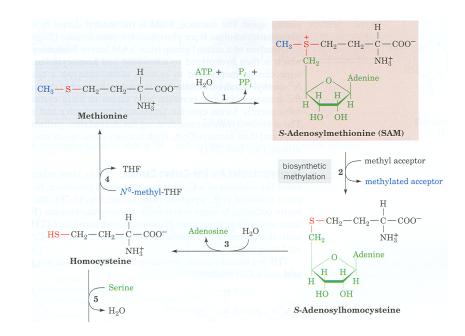

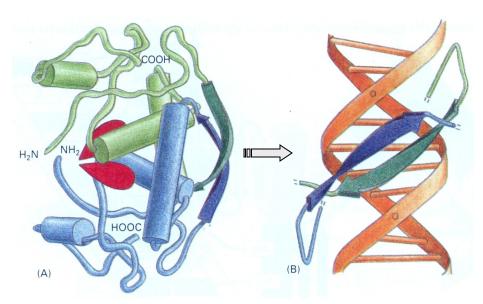

Usually single stranded

Bacteria

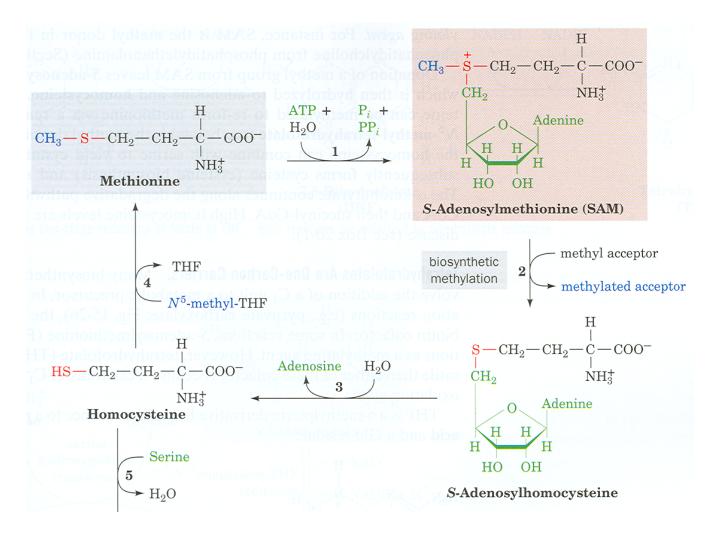

```
Triumph of proteins
80% of genome is coding DNA
Functionally diverse
    receptors
    motors
   catalysts
    regulators (Monod & Jakob, Nobel prize 1965)
```

Proteins catalyze & regulate biochemistry

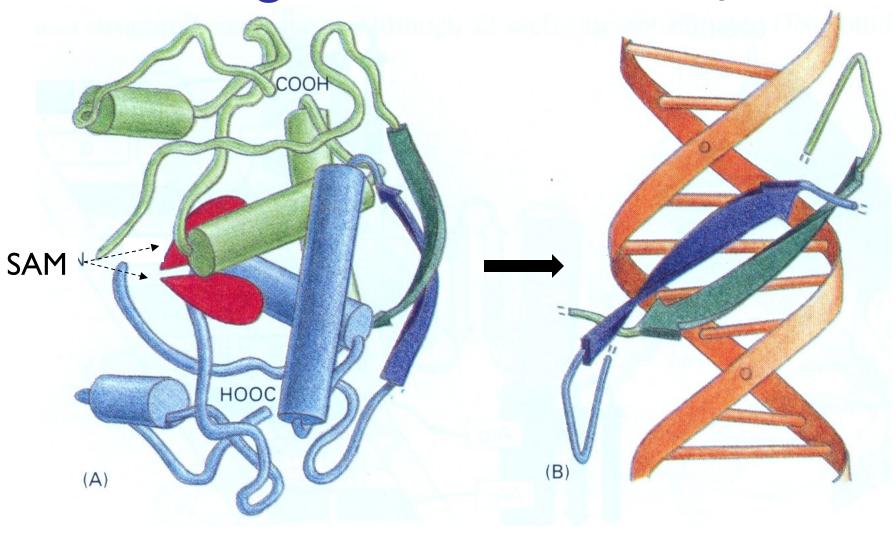

Met Pathways

Example: Glycine Regulation

How is glycine level regulated?

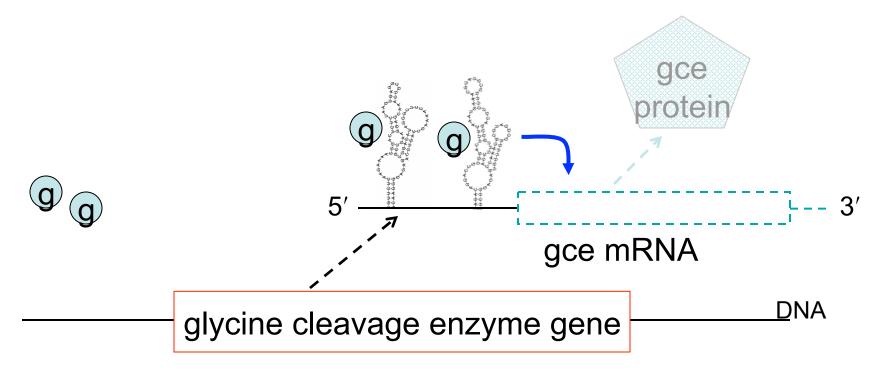

Plausible answer:

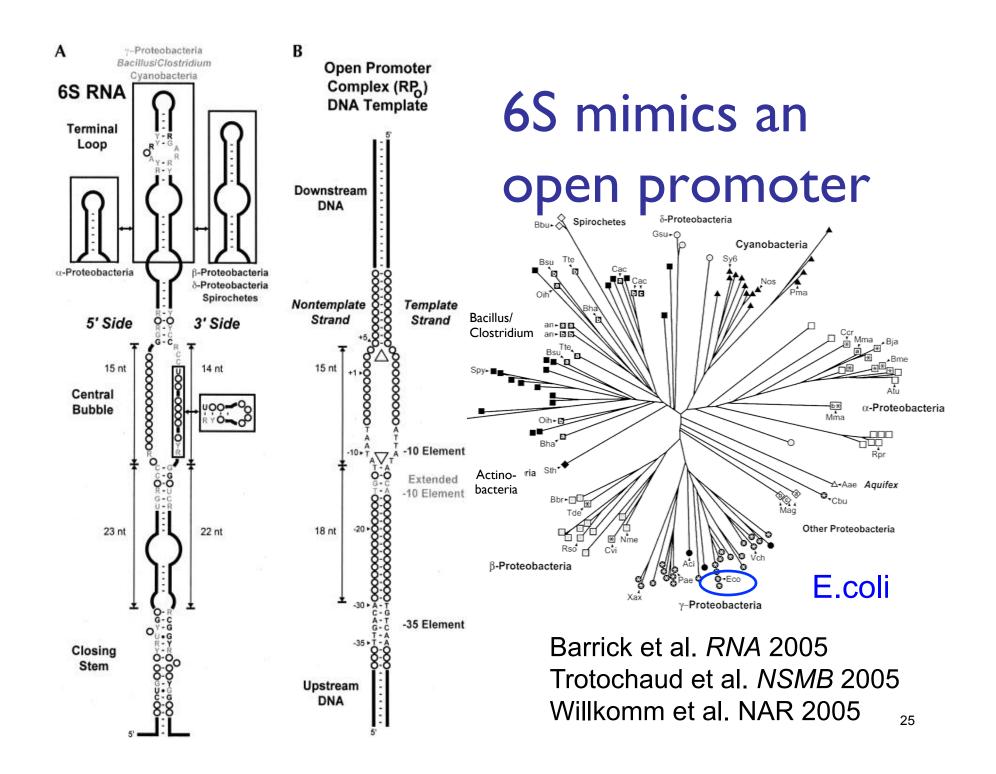

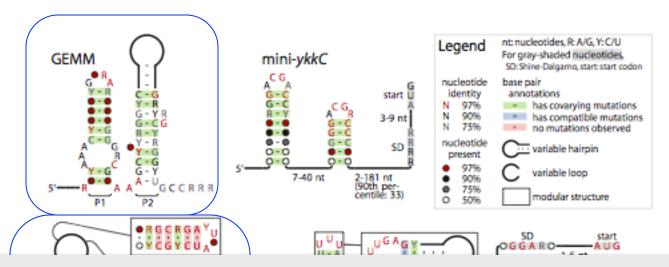

transcription factors (proteins) bind to DNA to turn nearby genes on or off

The Glycine Riboswitch

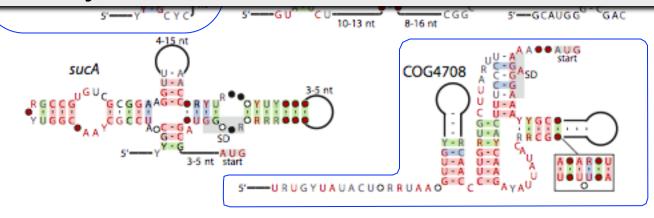

Actual answer (in many bacteria):

Widespread, deeply conserved, structurally sophisticated, functionally diverse, biologically important uses for ncRNA throughout prokaryotic world.

Vertebrates

Bigger, more complex genomes

<2% coding

But >5% conserved in sequence?

And 50-90% transcribed?

And structural conservation, if any, invisible (without proper alignments, etc.)

What's going on?

Vertebrate ncRNAs

mRNA, tRNA, rRNA, ... of course

PLUS:

snRNA, spliceosome, snoRNA, teleomerase, microRNA, RNAi, SECIS, IRE, piwi-RNA, XIST (X-inactivation), ribozymes, ...

MicroRNA

1st discovered 1992 in C. elegans
2nd discovered 2000, also C. elegans
and human, fly, everything between

21-23 nucleotides literally fell off ends of gels

Hundreds now known in human may regulate 1/3-1/2 of all genes development, stem cells, cancer, infectious diseases,...

siRNA

"Short Interfering RNA"

Also discovered in C. elegans

Possibly an antiviral defense, shares machinery with miRNA pathways

Allows artificial repression of most genes in most higher organisms

Huge tool for biology & biotech

ncRNA Characteristics

Often low levels

Can come from anywhere

Sense, antisense, introns, intergenic

Often poorly conserved

CDS: neutral ~ I0: I vs ncRNA: neutral ~ I.2: I

May suggest "transcriptional noise"

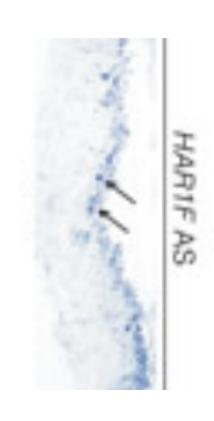

Noise?

HOWEVER:

Sometimes capped, spliced, polyA+

Some known ncRNAs are intronic (e.g. some miRNAs, all snoRNAs)

Sometimes very precisely localized to specific compartments, cell types, developmental stages, (esp. dev & neuronal ...)

Conservation?

Neutral rate underestimated?

Promoters also evolving rapidly

Sequence/function constraint for RNA ≠ CDS

Alignments are suspect away from CDS

Alignments are not optimized for RNA structure

Despite all this, there is evidence for purifying selection on ncRNA promoters, splice sites, tissue-specific expression patterns, indels, ...

Bottom line?

A significant number of "one-off" examples
Extremely wise-spread ncRNA expression
At a minimum, a vast evolutionary substrate
New technology (e.g. RNAseq) exposing
more

How do you recognize an interesting one?

Conserved secondary structure

Origin of Life?

Life needs

information carrier: DNA

molecular machines, like enzymes: Protein

making proteins needs DNA + RNA + proteins

making (duplicating) DNA needs proteins

Horrible circularities! How could it have arisen in an abiotic environment?

Origin of Life?

RNA can carry information, too

RNA double helix; RNA-directed RNA polymerase

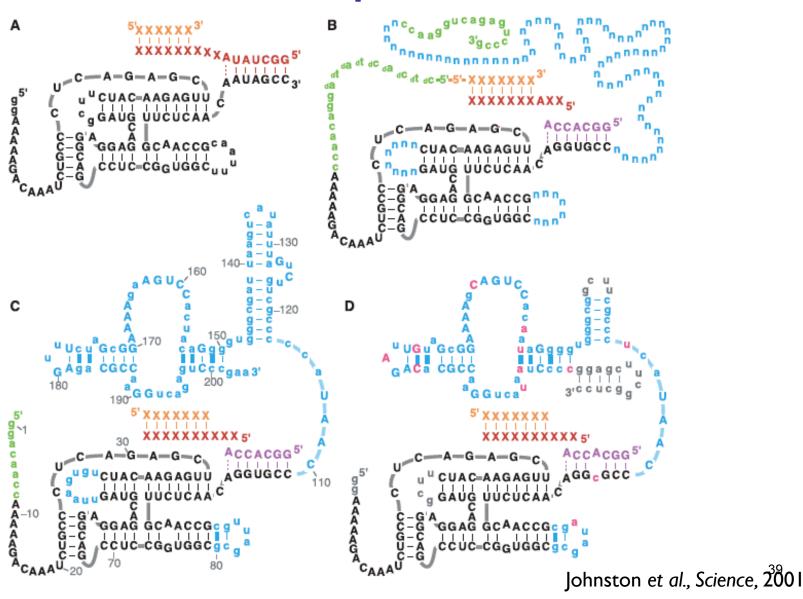

RNA can form complex structures

RNA enzymes exist (ribozymes)

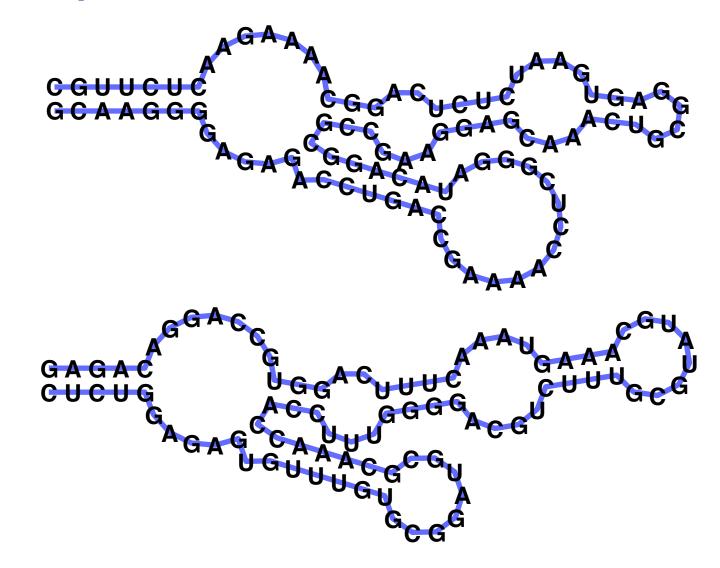

RNA can control, do logic (riboswitches)

The "RNA world" hypothesis: 1st life was RNA-based

RNA replicase

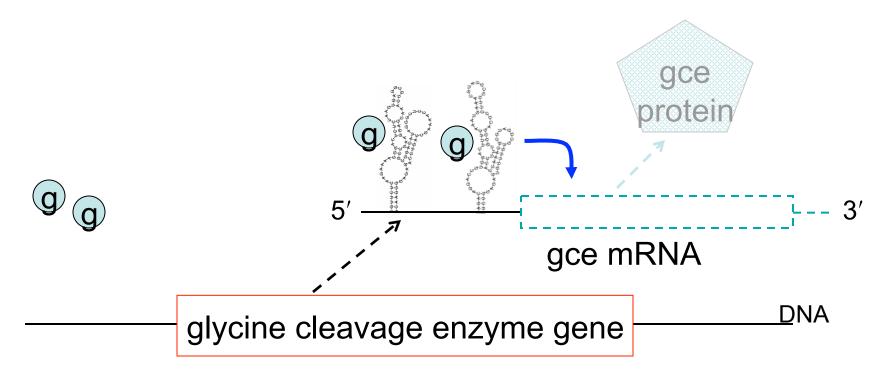

Why is RNA hard to deal with?

A: Structure often more important than sequence₅₀

The Glycine Riboswitch

Actual answer (in many bacteria):

Wanted

Good structure prediction tools
Good motif descriptions/models
Good, fast search tools
("RNA BLAST", etc.)
Good, fast motif discovery tools
("RNA MEME", etc.)

Importance of structure makes last 3 hard

Task I: Structure Prediction

RNA Structure

Primary Structure: Sequence

Secondary Structure: Pairing

Tertiary Structure: 3D shape

RNA Pairing

Watson-Crick Pairing

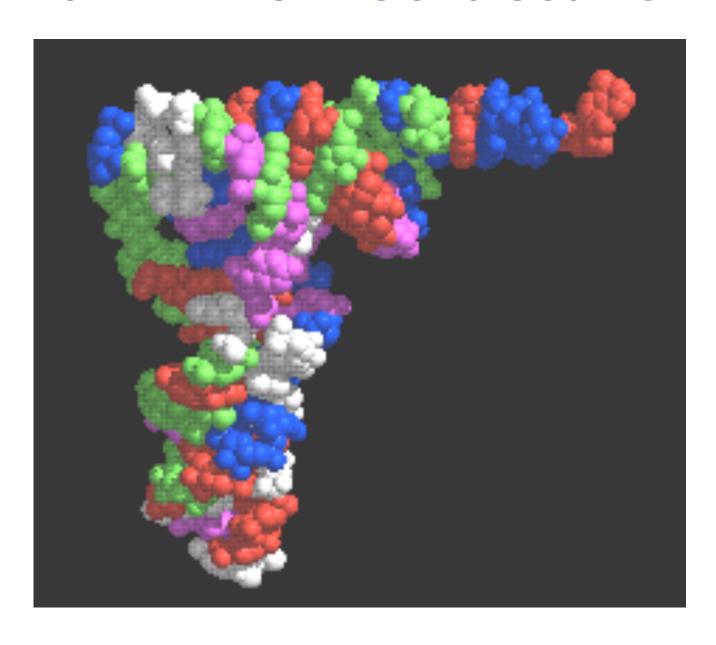

C - G ~ 3 kcal/mole

A - U ~ 2 kcal/mole

"Wobble Pair" G - U ~ | kcal/mole

Non-canonical Pairs (esp. if modified)

tRNA 3d Structure

tRNA - Alt. Representations

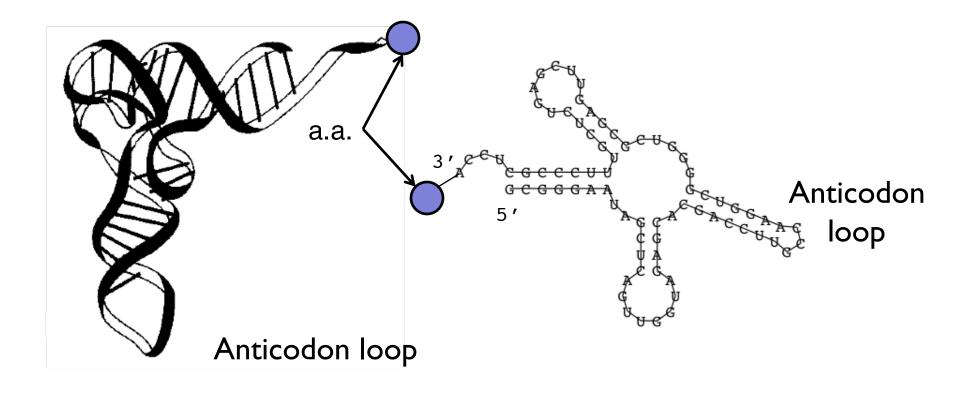

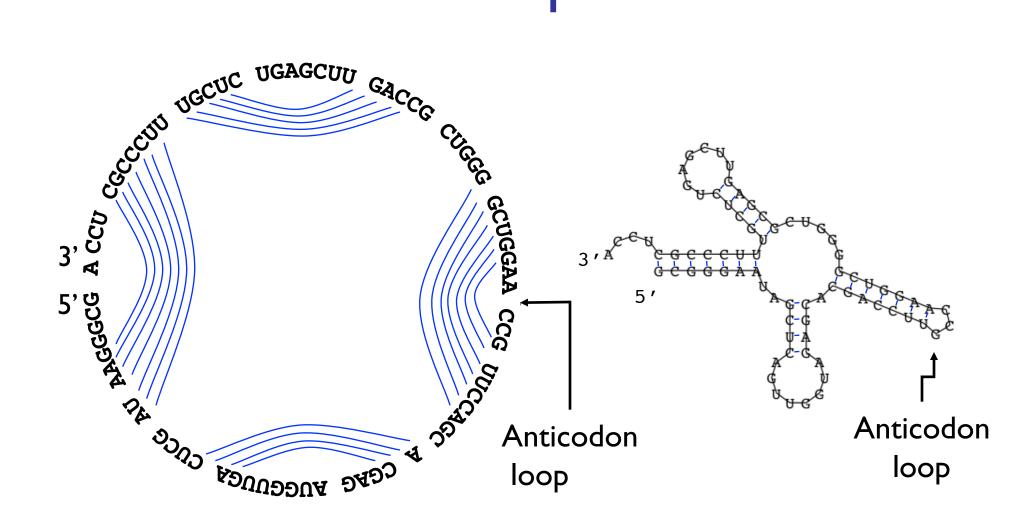

Figure 1: a) The spatial structure of the phenylalanine tRNA form yeast

b) The secondary structure extracts the most important information about the structure, namely the pattern of base pairings.

tRNA - Alt. Representations

Definitions

```
Sequence {}^{5'} r<sub>1</sub> r<sub>2</sub> r<sub>3</sub> ... r<sub>n</sub> {}^{3'} in {A, C, G, T}

A Secondary Structure is a set of pairs i•j s.t.

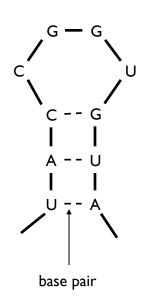

i < j-4, and \Big\} no sharp turns

if i•j & i'•j' are two different pairs with i \le i', then

j < i', or

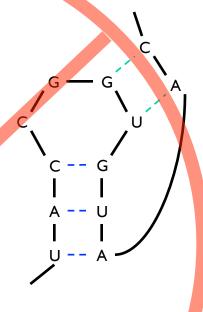

j < i',
```

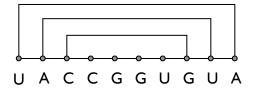

RNA Secondary Structure: Examples

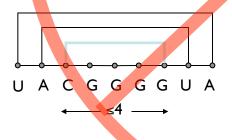

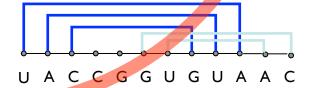

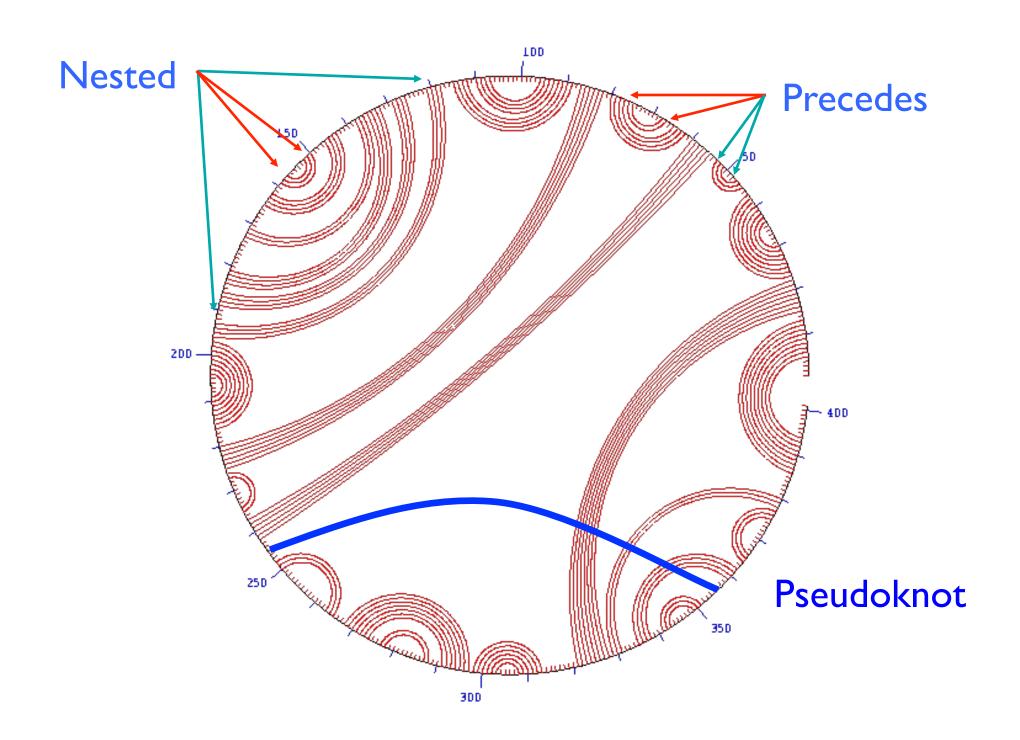

ok

sharp turn

crossing

Approaches to Structure Prediction

Maximum Pairing

- + works on single sequences
- + simple
- too inaccurate

Minimum Energy

- + works on single sequences
- ignores pseudoknots
- only finds "optimal" fold

Partition Function

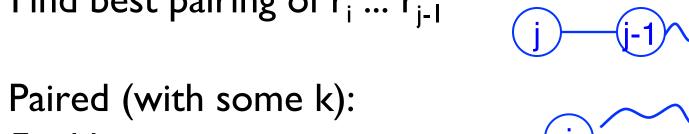

- + finds all folds
- ignores pseudoknots

Nussinov: Max Pairing

```
B(i,j) = \# \ pairs \ in \ optimal \ pairing \ of \ r_i \ ... \ r_j
B(i,j) = 0 \ for \ all \ i, \ j \ with \ i \ge j-4; \ otherwise
B(i,j) = \max \ of:
\left\{ \begin{array}{l} B(i,j-1) \\ \max \ \{ \ B(i,k-1)+1+B(k+1,j-1) \ | \\ i \le k < j-4 \ and \ r_k-r_j \ may \ pair \right\}
```

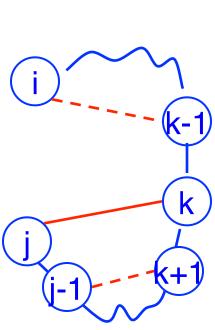

"Optimal pairing of r_i ... r_j " Two possibilities

j Unpaired: Find best pairing of $r_i \dots r_{j-1}$

Find best $r_i \dots r_{k-1} +$ best $r_{k+1} \dots r_{j-1}$ plus I

Why is it slow? Why do pseudoknots matter?

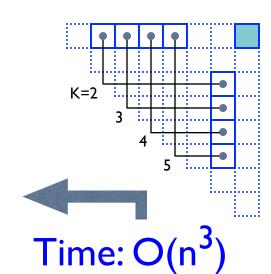

Nussinov:

A Computation Order

B(i,j) = # pairs in optimal pairing of $r_i \dots r_j$

B(i,j) = 0 for all i, j with $i \ge j-4$; otherwise

 $B(i,j) = \max of:$

Which Pairs?

Usual dynamic programming "trace-back" tells you which base pairs are in the optimal solution, not just how many

Pair-based Energy Minimization

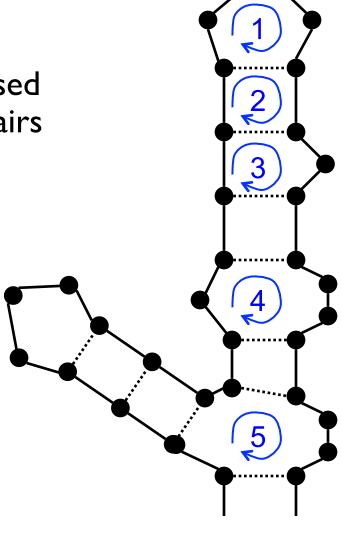

```
E(i,j) = \text{energy of pairs in optimal pairing of } r_i \dots r_j
E(i,j) = \infty \text{ for all } i, j \text{ with } i \ge j\text{-4}; \text{ otherwise}
E(i,j) = \min \text{ of:}
\left\{ E(i,j\text{-1}) \right\} \quad \text{energy of } k\text{-}j \text{ pair}
\min \left\{ E(i,k\text{-}1) + e(r_k, r_j) + E(k\text{+}1,j\text{-}1) \mid i \le k < j\text{-}4 \right\}
\text{Time: } O(n^3) \quad \text{
```

Loop-based Energy Minimization

Detailed experiments show it's more accurate to model based on loops, rather than just pairs

Loop types

- I. Hairpin loop
- 2. Stack
- 3. Bulge
- 4. Interior loop
- 5. Multiloop

Zuker: Loop-based Energy, I

```
\begin{split} W(i,j) &= \text{energy of optimal pairing of } r_i \dots r_j \\ V(i,j) &= \text{as above, but forcing pair } i \bullet j \\ W(i,j) &= V(i,j) = \infty \text{ for all } i, j \text{ with } i \geq j-4 \\ W(i,j) &= \min(W(i,j-1), \\ \min \big\{ W(i,k-1) + V(k,j) \mid i \leq k \leq j-4 \big\} \\ \big) \end{split}
```

Zuker: Loop-based Energy, II

```
bulge/
                                                         multi-
                hairpin
                          stack
                                               interior
                                                         loop
V(i,j) = min(eh(i,j), es(i,j)+V(i+1,j-1), VBI(i,j), VM(i,j))
VM(i,j) = min \{ W(i,k)+W(k+1,j) \mid i < k < j \}
VBI(i,j) = min \{ ebi(i,j,i',j') + V(i', j') \}
                          i < i' < i' < i \& i'-i+j-j' > 2 
                                                    Time: O(n^4)
          bulge/
         interior
                           O(n<sup>3</sup>) possible if ebi(.) is "nice"
```

Energy Parameters

- Q. Where do they come from?
- A1. Experiments with carefully selected synthetic RNAs
- A2. Learned algorithmically from trusted alignments/structures

[Andronescu et al., 2007]

Accuracy

Latest estimates suggest ~50-75% of base pairs predicted correctly in sequences of up to ~300nt

Definitely useful, but obviously imperfect

Approaches to Structure Prediction

Maximum Pairing

- + works on single sequences
- + simple
- too inaccurate

Minimum Energy

- + works on single sequences
- ignores pseudoknots
- only finds "optimal" fold

Partition Function

- + finds all folds
- ignores pseudoknots

Approaches, II

Comparative sequence analysis

- + handles all pairings (potentially incl. pseudoknots)
- requires several (many?) aligned, appropriately diverged sequences

Stochastic Context-free Grammars
Roughly combines min energy & comparative,
but no pseudoknots

Physical experiments (x-ray crystalography, NMR)

Summary

RNA has important roles beyond mRNA Many unexpected recent discoveries

Structure is critical to function

True of proteins, too, but they're easier to find from sequence alone due, e.g., to codon structure, which RNAs lack

RNA secondary structure can be predicted (to useful accuracy) by dynamic programming

Next: RNA "motifs" (seq + 2-ary struct) well-captured by "covariance models"
