Outline

- **Review of ACID properties**
  - Today we will cover techniques for ensuring atomicity and durability in face of failures
- **Review of buffer manager and its policies**
- **Write-ahead log + simple UNDO / REDO recovery**
- **ARIES method for failure recovery**

ACID Properties

- Atomicity: Either all changes performed by transaction occur or none occurs
- Consistency: A transaction as a whole does not violate integrity constraints
- Isolation: Transactions appear to execute one after the other in sequence
- Durability: If a transaction commits, its changes will survive failures

What Could Go Wrong?

- Concurrent operations
  - That's what we discussed last time (atomicity and isolation properties)

- Failures can occur at any time
  - Today (isolation and durability properties)

Problem Illustration

Client 1:

```
START TRANSACTION
INSERT INTO SmallProduct(name, price)
        SELECT pname, price
        FROM Product
        WHERE price <= 0.99

DELETE Product
        WHERE price <=0.99
COMMIT
```

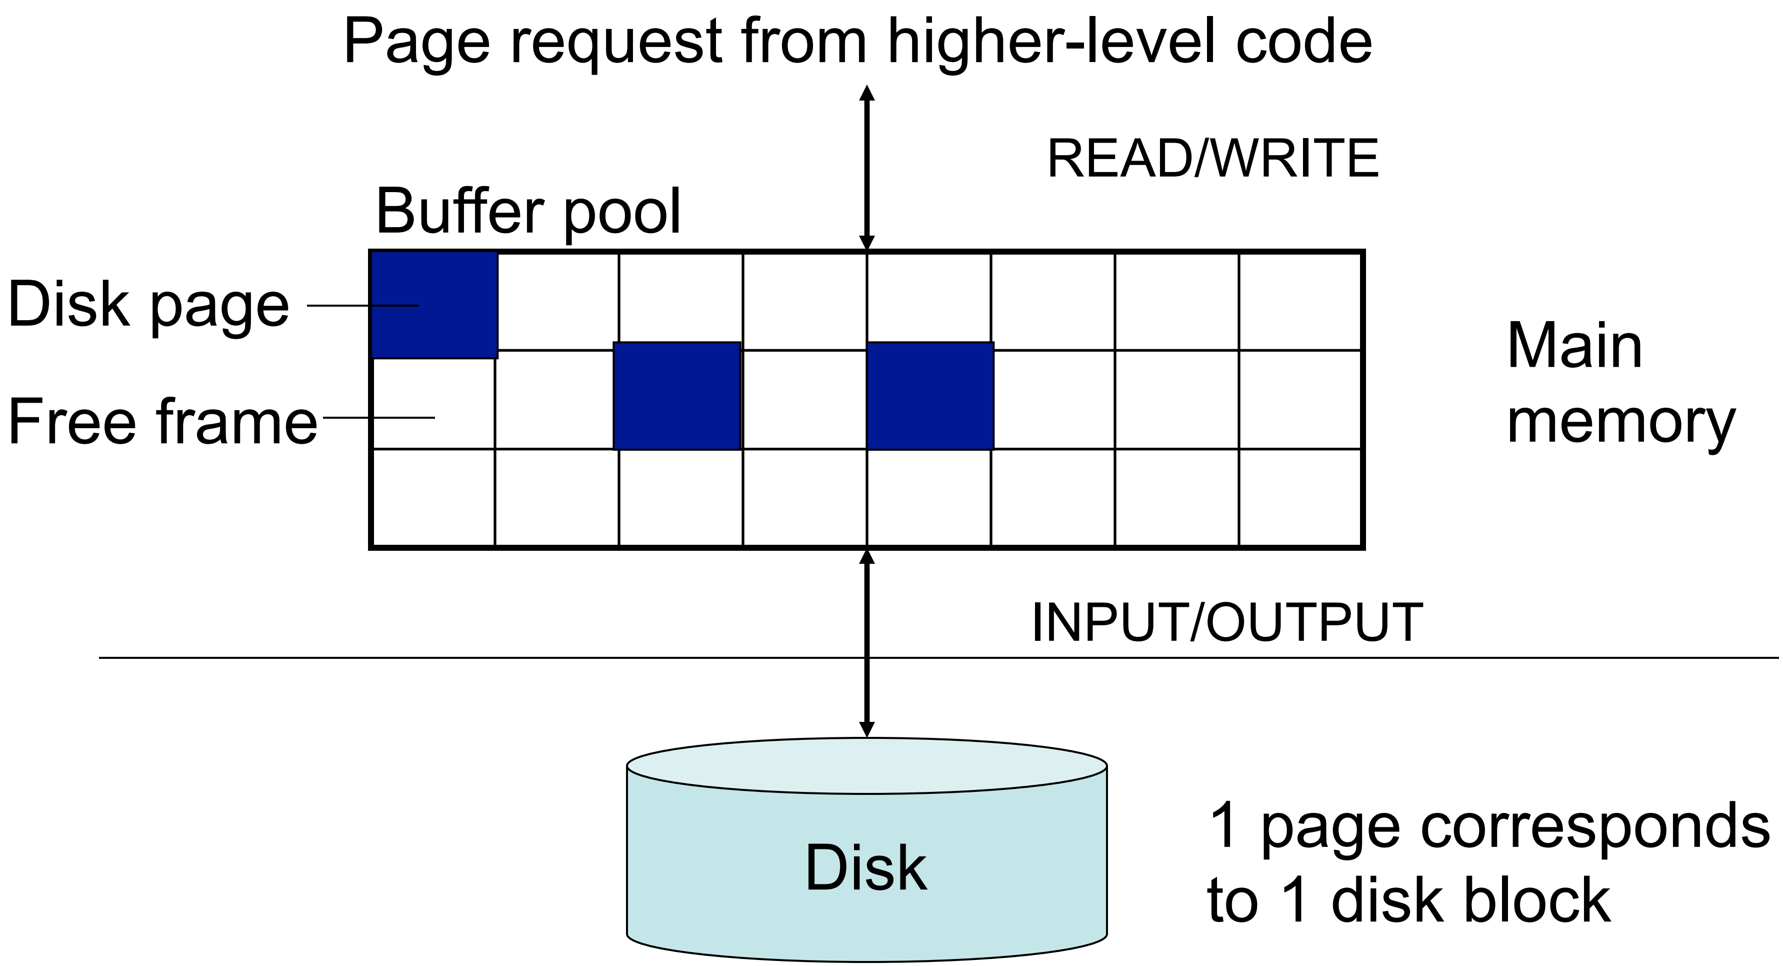
Crash !

What do we do now?

Handling Failures

- Types of failures
  - Transaction failure
  - System failure
  - Media failure -> we will not talk about this now
- Required capability: undo and redo
- Challenge: buffer manager
  - Changes performed in memory
  - Changes written to disk only from time to time

Impact of Buffer Manager



1 page corresponds to 1 disk block

Primitive Operations

- READ(X,t)
  - copy value of data item X to transaction local variable t
- WRITE(X,t)
  - copy transaction local variable t to data item X

- INPUT(X)
  - read page containing data item X to memory buffer
- OUTPUT(X)
  - write page containing data item X to disk

Running Example

```
BEGIN TRANSACTION
READ(A,t);
t := t*2;
WRITE(A,t);
READ(B,t);
t := t*2;
WRITE(B,t)
COMMIT;
```

Initially, A=B=8.

Atomicity requires that either
(1) T commits and A=B=16, or
(2) T does not commit and A=B=8.

READ(A,t); t := t*2; WRITE(A,t);
READ(B,t); t := t*2; WRITE(B,t)

Write-Ahead Log

- **Log: append-only file containing log records**
- For every update, commit, or abort operation
  - Write a log record
  - Multiple transactions run concurrently, log records are interleaved
- After a system crash, use log to:
  - Redo transactions that did commit
  - Undo other transactions that didn't commit

Log Granularity

Two basic types of log records for update operations

- Physical log records
  - Position on a particular page where update occurred
  - Both before and after image for undo/redo logs
  - Benefits: Idempotent & updates are fast to redo/undo
- Logical log records
  - Record only high-level information about the operation
  - Benefit: Smaller log
  - BUT difficult to implement because crashes can occur in the middle of an operation

Buffer Manager Policies

- **STEAL or NO-STEAL**
  - Can an update made by an uncommitted transaction overwrite the most recent committed value of a data item on disk?
- **FORCE or NO-FORCE**
  - Should all updates of a transaction be forced to disk before the transaction commits?
- Easiest for recovery: **NO-STEAL**/**FORCE**
- Highest performance: **STEAL**/**NO-FORCE**

COMMIT				FORCE		<COMMIT T>

RULES: log entry *before* OUTPUT *before* COMMIT

Undo-Logging Rules

U1: If T modifies X, then <T,X,v> must be written to disk before OUTPUT(X)

U2: If T commits, then OUTPUT(X) must be written to disk before <COMMIT T>

FORCE

- Hence: OUTPUTs are done *early*, before the transaction commits

REDO Log

NO-FORCE and NO-STEAL

Redo Logging

One minor change to the undo log:

- <T,X,v>= T has updated element X, and its *new* value is v

ARIES

Aries

- ARIES pieces together several techniques into a comprehensive algorithm
- Developed at IBM Almaden, by Mohan
- IBM botched the patent, so everyone uses it now
- Several variations, e.g. for distributed transactions

Granularity in ARIES

- *Physiological logging*
  - Log records refer to a single page
  - But record logical operation within the page

- Page-oriented logging for REDO
  - Necessary since can crash in middle of complex operation
- Logical logging for UNDO
  - Enables **tuple-level locking**!
  - Why physical logging for REDO and logical logging for UNDO? (answer at the end of the lecture)

ARIES Method

Recovery from a system crash is done in 3 passes:

1. **Analysis pass**
   - Figure out what was going on at time of crash
   - List of dirty pages and active transactions
2. **Redo pass (repeating history principle)**
   - Redo all operations, even for transactions that will not commit
   - Get back to state at the moment of the crash
3. **Undo pass**
   - Remove effects of all uncommitted transactions
   - Log changes during undo in case of another crash during undo

ARIES Recovery Manager

- A redo/undo log
- Physiological logging
  - Physical logging for REDO
  - Logical logging for UNDO
- Efficient checkpointing

Why do we
do checkpointing?

ARIES Recovery Manager

Log entries:

- <START T> -- when T begins
- Update: <T,X,u,v>
  - T updates X, *old* value=u, *new* value=v
  - In practice: *undo only* and *redo only* entries
- <COMMIT T> or <ABORT T>
- CLR's – we'll talk about them later.

ARIES Recovery Manager

Rule:

- If T modifies X, then <T,X,u,v> must be written to disk before OUTPUT(X)

We are free to OUTPUT early or late

LSN = Log Sequence Number

- **LSN** = identifier of a log entry
  - Log entries belonging to the same TXN are linked
- Each page contains a **pageLSN**:
  - LSN of log record for latest update to that page

ARIES Data Structures

- **Active Transactions Table**
  - Lists all active TXN's
  - For each TXN: lastLSN = its most recent update LSN
- **Dirty Page Table**
  - Lists all dirty pages
  - For each dirty page: recoveryLSN (recLSN)= first LSN that caused page to become dirty
- **Write Ahead Log**
  - LSN, prevLSN = previous LSN for same txn

ARIES Normal Operation

T writes page P

- What do we do ?

ARIES Normal Operation

T writes page P

- What do we do ?

- Write **<T,P,u,v>** in the **Log**
- **prevLSN=lastLSN**
- **pageLSN**=**LSN**
- **lastLSN**=**LSN**
- **recLSN**=if isNull then **LSN**

ARIES Normal Operation

Buffer manager wants to OUTPUT(P)

- What do we do ?

Buffer manager wants INPUT(P)

- What do we do ?

ARIES Normal Operation

Buffer manager wants to OUTPUT(P)

- Flush log up to **pageLSN**
- Remove P from **Dirty Pages** table

Buffer manager wants INPUT(P)

- Create entry in **Dirty Pages** table
  recLSN = NULL

ARIES Normal Operation

Transaction T starts

- What do we do ?

Transaction T commits/aborts

- What do we do ?

ARIES Normal Operation

Transaction T starts

- Write **<START T>** in the log
- New entry T in Active TXN;
  lastLSN = null

Transaction T commits/aborts

- Write **<COMMIT T>** in the log
- Flush log up to this entry

Checkpoints

Write into the log

- Entire active transactions table
- Entire dirty pages table

Recovery always starts by analyzing latest checkpoint

Background process periodically flushes dirty pages to disk

ARIES Recovery

1. **Analysis pass**
   - Figure out what was going on at time of crash
   - List of dirty pages and active transactions
2. **Redo pass (repeating history principle)**
   - Redo all operations, even for transactions that will not commit
   - Get back to state at the moment of the crash
3. **Undo pass**
   - Remove effects of all uncommitted transactions
   - Log changes during undo in case of another crash during undo

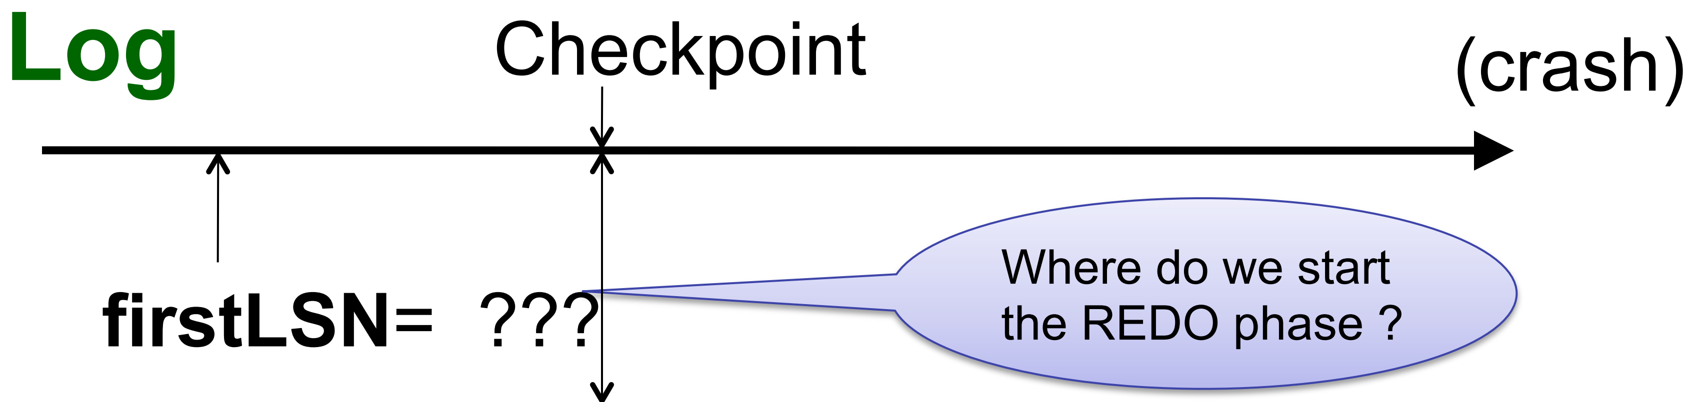
First undo and first redo log entry might be in reverse order

[Figure 3 from Franklin97]

1. Analysis Phase

- Goal
  - Determine point in log (**firstLSN**) where to start REDO
  - Determine set of dirty pages when crashed
    - Conservative estimate of dirty pages
  - Identify active transactions when crashed
- Approach
  - Rebuild active transactions table and dirty pages table
  - Reprocess the log from the checkpoint
    - Only update the two data structures
  - Compute: **firstLSN** = smallest of all recoveryLSN

1. Analysis Phase



Dirty pages

pageID	recLSN	pageID

Active txn

transID	lastLSN	transID

1. Analysis Phase

firstLSN=min(**recLSN**)

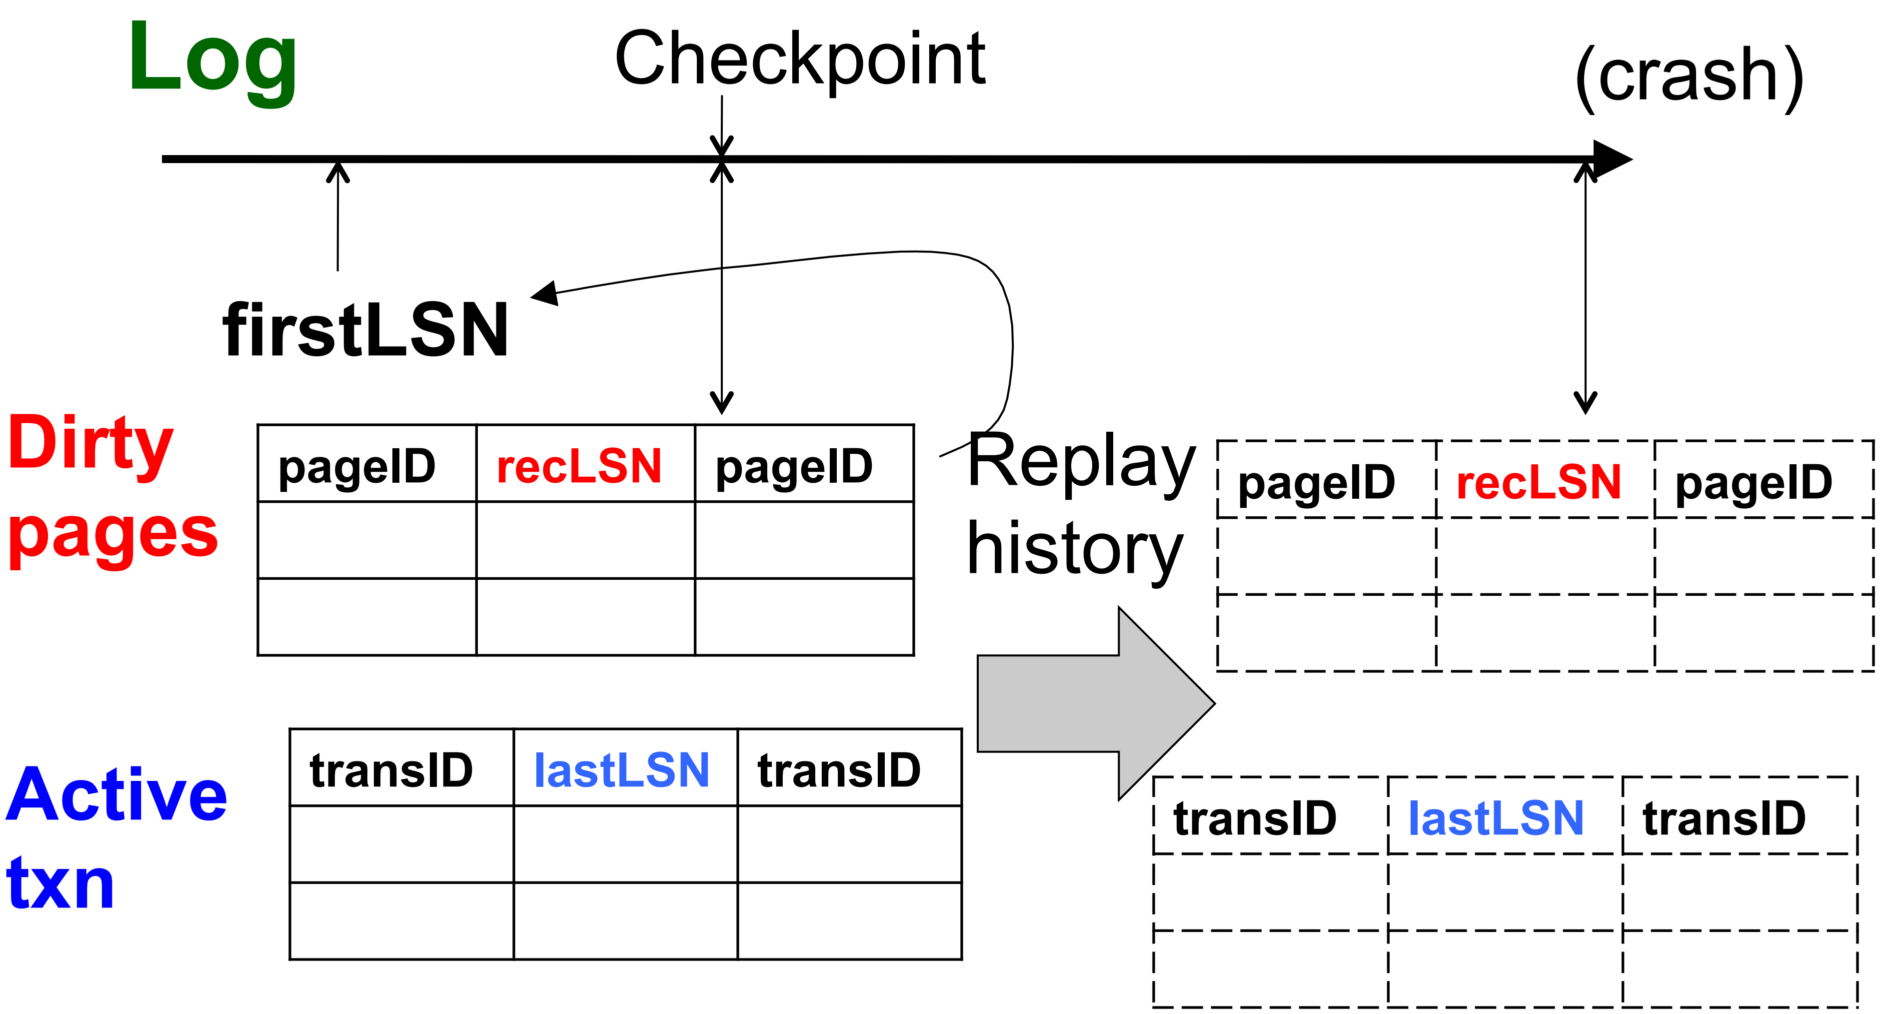
Dirty pages

pageID	recLSN	pageID

Active txn

transID	lastLSN	transID

1. Analysis Phase



2. Redo Phase

Main principle: replay history

- Process Log forward, starting from **firstLSN**
- Read every log record, sequentially
- Redo actions are not recorded in the log
- Needs the Dirty Page Table

2. Redo Phase: Details

For each Log entry record LSN: **<T,P,u,v>**

- Re-do the action P=u and WRITE(P)
- But which actions can we skip, for efficiency ?

2. Redo Phase: Details

For each Log entry record LSN: **<T,P,u,v>**

- If P is not in Dirty Page then **no update**
- If recLSN > LSN, then **no update**
- Read page from disk:
  If **pageLSN** > LSN, then **no update**
- Otherwise perform update

2. Redo Phase: Details

What happens if system crashes during REDO ?

2. Redo Phase: Details

What happens if system crashes during REDO ?

We REDO again ! Each REDO operation is *idempotent*: doing it twice is the as as doing it once.

3. Undo Phase

- Cannot “unplay” history, in the same way as we “replay” history
- WHY NOT ? Time to answer this question☺

3. Undo Phase

- Cannot “unplay” history, in the same way as we “replay” history
- WHY NOT ? Time to answer this question☺
- Need to support ROLLBACK!
  Selective undo, for one transaction only
  - Cannot simply undo physical actions
  - E.g. Txn updates a record on a page, another Txn updates another record on the same page: don’t undo the latter
  - E.g. Txn updates a B^+-tree, causing rebalancing, other Txn do other update: don’t undo the latter!
- Hence, *logical* undo v.s. *physical* redo

3. Undo Phase

Main principle: "logical" undo

- Start from end of Log, move backwards
- Read only affected log entries
- Undo actions *are* written in the Log as special entries: CLR (Compensating Log Records)
- CLRs are redone, but never undone

3. Undo Phase: Details

- "Loser transactions" =
  - Uncommitted transactions in Active Transactions Table
  - Or transactions to be rolled back

- **ToUndo** = set of lastLSN of loser transactions

3. Undo Phase: Details

While **ToUndo** not empty:

- Choose most recent (largest) LSN in **ToUndo**
- If LSN = regular record **<T,P,u,v>**:
  - Undo v
  - Write a CLR where CLR.undoNextLSN = LSN.prevLSN
- If LSN = CLR record:
  - Don’t undo !
- if CLR.**undoNextLSN** not null, insert in **ToUndo** otherwise, write **<END TRANSACTION>** in log

3. Undo Phase: Details

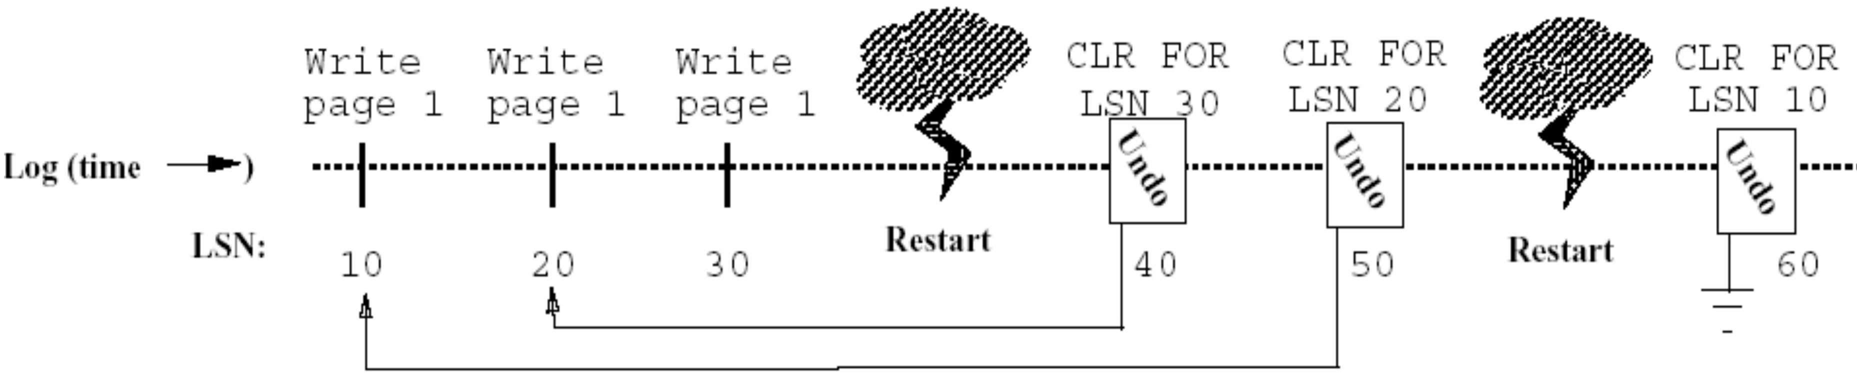


Figure 4: The Use of CLRs for UNDO

[Figure 4 from Franklin97]

3. Undo Phase: Details

What happens if system crashes during UNDO ?

3. Undo Phase: Details

What happens if system crashes during UNDO ?

We do not UNDO again ! Instead, each CLR is a REDO record: we simply redo the undo

Physical v.s. Logical Loging

Why are redo records *physical* ?

Why are undo records *logical* ?

Physical v.s. Logical Loging

Why are redo records ***physical*** ?

- Simplicity: replaying history is easy, and idempotent

Why are undo records ***logical*** ?

- Required for transaction rollback: this not "undoing history", but selective undo
