---

## Outline for Today

- Quick Review
  - ArrayList collections; add, size, get, etc. methods
  - Iteration and while loops
- Today
  - Iterating through collections
  - Iterator objects

5/7/2004

---

## Using Collections

- We can create ArrayLists, and put things into them.

```
ArrayList names = new ArrayList();
names.add("Bob");
names.add("Sue");
names.add("Jeremiah");
```

- We can pick out elements at particular index positions.

```
String someNames = names.get(0) + " and " + names.get(1);
```

- But how can we do something for all names?

- Print out all names in the list.
- Find the first name, alphabetically.
- Find what the longest name.
- See if a given name is in the list.

## Iterating The Old-Fashioned Way

- Using what we already know about ArrayLists, we can iterate as follows:

```
for (int rnum = 0; rnum < myList.size(); rnum++) {
    ElementType oneItem = (ElementType) myList.get(rnum);
    // process this item
    ...
}
```

## Walking Down the List

- Abstractly, what we really want is to be able to write:

For all elements in the list,  
Do something.

- To get "all elements in the list", we can use an *iterator*
- An iterator helps us "walk down the list"

M-5

## Iterator Objects

- An iterator is an object that stands as an intermediary between us and the data structure
  - It knows how many items there are in the structure
  - It keeps track of which ones it has passed out
  - We don't have to know how many elements are in the list!
- Strategy:
  - Ask the array list for its iterator object.
  - Ask the iterator object for each element, in turn, as part of a loop.

## Iterator Operations

- Getting an iterator object from an ArrayList (and many other kinds of Java collections):

```
Iterator iter = names.iterator();
```

- Here are the two methods provided by Iterator:

```
// Return true if the iteration has more elements.  
public boolean hasNext();
```

```
// Return the next element in the iteration.  
public Object next();
```

## Using an Iterator, in English

- General algorithm:

```
Get the iterator for the collection [names.iterator()].  
While the iterator has at least one more element [iter.hasNext()],  
    Get the next element [iter.next()].  
    Do something using the element.  
    Then go back to the top.  
Otherwise, we're done.
```

- This is a very common and very important pattern in programming

## Using an Iterator, in Java

```
ArrayList names = ...;

System.out.println("The names are as follows:");

Iterator iter = names.iterator();    // get the iterator for the collection.

while ( iter.hasNext() ) {          // while there is another element...
    String name = (String) iter.next(); // get the element (and cast it if needed)
    System.out.println(name);        // do something using the element.
}                                    // then go back to the top.

// Otherwise, we're done.
```

## Relationship between List and Iterator

- A drawing helps clarify it...

M-10

## Example: Finding the Longest Name

- Suppose we want to find the longest name in a list. How would we do it?
  - Recall: "Bob".length() == 3
- What's the algorithm in English?
- What's the Java code?

## Solution

5/7/2004

(c) 2001-3, University of Washington

M-12

## Iterators vs Indexed Access

- We can also process an ArrayList using get(index)

```
for (int k = 0; k < names.size(); k++) {  
    process names.get(k);  
}
```

- Tradeoffs

- Iterators are more general – work on all collections, even if the collection doesn't support indexed access (i.e., using get(k) to access elements directly)
- Iterators by default only support traversal of a collection from beginning to end.

Some types of collections have special iterators to allow going in reverse

- **General rule: use iterators (the more general solution) normally; use other traversals when iterators don't do what you need**
