## A Programming Task

- Suppose we wish to give each HuskyCard a unique serial number

```
class HuskyCard {  
    private String accountName;    // account holder's name  
    private double balance;        // account balance  
    private int accountNumber;     // unique account number  
    ...  
}
```

- We'd like the constructor to assign unique account numbers as HuskyCard objects are created
  - Don't want to depend on client code supplying the number

S-2

---

## HuskyCard Constructor

- First Attempt

```
class HuskyCard {  
    ...  
    // construct new HuskyCard with given name, balance, and unique acct #  
    public HuskyCard(String accountName, double initialBalance) {  
        this.accountName = accountName;  
        this.balance = initialBalance;  
        this.accountNumber = nextAvailableAccountNumber;  
        nextAvailableAccountNumber++;  
    }  
    ...  
}
```

- Questions: Where (what) is nextAvailableAccountNumber?  
Where is it stored?

S-3

---

## What is nextAvailableAccountNumber?

- Instance variable?
  - No – we don't want one of these per object (class instance)
- Local variable in the constructor?
  - No – we need to retain next available value between creation of one object and the next
- Answer: we need a *single* copy somewhere, not associated with any particular object
- Solution: have one copy that's associated with class HuskyCard itself, not with individual instances

S-4

## Static Variables

- A *static* variable is one that belongs to the class itself
- Single, unique copy shared by all instances
- Usually initialized in its declaration

```
class HuskyCard {
    // object instance variables:
    private String accountName;    // account holder's name
    private double balance;        // account balance
    private int accountNumber;     // unique account number

    // class variables:
    static private int nextAvailableAccountNumber = 1; // next available acct #
    ...
}
```

S-5

## HuskyCard Constructor (Fixed Version)

- Now we're all set

```
class HuskyCard {
    ...
    // construct new HuskyCard with given name, balance, and unique acct #
    public HuskyCard(String accountName, double initialBalance) {
        this.accountName = accountName;
        this.balance = initialBalance;
        this.accountNumber = HuskyCard.nextAvailableAccountNumber;
        HuskyCard.nextAvailableAccountNumber++;
    }
    ...
}
```

- Can refer to a static variable here without using class name (Why?)

(Java even allows `this.nextAvailableAccountNumber`, but that seems very misleading)

S-6

## Draw the Picture

```
HuskyCard mine = new HuskyCard("Teacher", 170.42);
HuskyCard yours = new HuskyCard("Former Student", 4351769.17);
```

S-7

## Symbolic Constants: Static Final Variables

- Sometimes we just want to give a name to a constant value, like pi or e or the number of gallons per liter
- Solution: a static variable, but further qualified with *final* so it can't be changed after it is initialized

```
/** An important number */
public static final double PI = 3.1415926535;
```

- Final variables must be initialized when declared; cannot be changed later
- Any variable that won't be changed after initialization can be marked final

S-8

## Constants in the Java Libraries

- Several Java classes contain useful named constants
- Class Math contains PI and E, with the expected values  
`area = Math.PI * radius * radius;`
- Classes like Integer and Double contain things like the largest possible int value, the smallest positive non-zero double, etc
- The Color class has static final variables for many predefined colors (Color.green, etc.)

S-9

## Static Methods

- Some methods in Java aren't naturally associated with particular objects
  - Basic math functions – sqrt, sin, cos, tan
- Other methods we might want to call before we've created any instance of a class, or that provide a way to create an object aside from a constructor
  - `newInputFromFile(String fileName)` in the Input class
  - test methods
- Such methods can be declared *static*: the method is not part of any instance, but rather the class itself
  - Invoked by sending a message to the class itself
  - Cannot access `this` or any instance variables or methods inside a static method since there's no associated object (instance)

S-10

## Class Math

- Example: Math (class in standard Java library)

```
public class Math {  
    public static final double PI = 3.1415926535;  
    public static final double E = 2.71828;  
    public static double sqrt(double x) { ... }  
    public static double sin(double x) { ... }  
    ...  
}
```

- Example of use:

```
double distance = Math.sqrt(dx*dx + dy*dy);
```

S-11

## Method main

- We now can understand the definition of main methods  
`public static void main(String[] args) { ... }`
- Static – it belongs to a class, not an instance of a class
  - So it can be executed without creating any objects first
- Typical contents of main: create some objects and call a method or two to get things going
- args array contains any string arguments passed to the program when it was started (command line or other interface, depending on particular implementation)
  - Actual name can be whatever you want, not necessarily args
