CSE 142, Summer 2008

Programming Assignment #7: Personality Test (20 points) Due: Thursday, August 14, 2008, 11:00 PM

This assignment focuses on arrays and file processing. Turn in a file named PersonalityTest.java. You will also need input file personality.txt from the course web site. Save this file in the same folder as your program.

The assignment involves processing data from a personality test. There is a link on the course web site where you can take the personality test yourself. Student answers will be included in a data file distributed to the whole class.

Background Information:

The Keirsey Temperament Sorter (http://www.keirsey.com/) is a personality test that involves answering 70 questions. Each question has two answer choices, which we will refer to as the "A" and "B" answer. The person taking the test is allowed to leave a question blank, in which case the answer will be recorded with a dash ('--').

The Keirsey test measures four independent dimensions of personality:

- 1. <u>Extrovert versus Introvert</u> (E vs I): what energizes you
- 2. Sensation versus iNtuition (S vs N): what you focus on
- 3. Thinking versus Feeling (T vs F): how you interpret what you focus on
- 4. Judging versus Perceiving (J vs P): how you approach life

Individuals are categorized as being on one side or the other for each dimension. The corresponding letters are put together to form a personality type. For example, if you are an <u>Extrovert</u>, i<u>N</u>tuitive, <u>Thinking</u>, <u>Perceiving</u> person then you are referred to as an ENTP. The "A" answers correspond to E, S, T, and J (the left-hand choices above). The "B" answers correspond to I, N, F, and P (the right-hand choices above). For each dimension, we determine a percentage of B answers the user gave for that dimension between 0 and 100, to indicate whether the person is closer to the "A" or "B" side.

Suppose that someone's answers are as follows (These are the answers given by "Betty Boop" later in this document).

| Dimension | # of "A" answers | # of "B" answers | % of "B" answers | Result |
|---------------------|------------------|------------------|------------------|--------|
| Extrovert/Introvert | 1 | 9 | 90% | I |
| Sensing/iNtuition | 17 | 3 | 15% | S |
| Thinking/Feeling | 18 | 2 | 10% | T |
| Judging/Perceiving | 18 | 2 | 10% | J |

We add up how many of each type of answer we got for each dimension. Then we compute the percentage of B answers for each dimension. Then we assign letters based on which side the person ends up on for each dimension. In the Extrovert/Introvert dimension, for example, Betty gave 9 "B" answers out of 10 total (90%), which means she is on the B side, which is "Introvert" or I. The overall percentages are (90, 15, 10, 10) which works out to a personality type of ISTJ.

Mechanics of the Personality Test:

The questions are organized into 10 groups of 7 questions, with the following repeating pattern in each group:

- 1. The first one question in each group is an Introvert/Extrovert question (questions 1, 8, 15, 22, etc).
- 2. The next two questions are for Sensing/iNtuition (questions 2 and 3, 9 and 10, 16 and 17, 23 and 24, etc).
- 3. The next two questions are for Thinking/Feeling (questions 4 and 5, 11 and 12, 18 and 19, 25 and 26, etc).
- 4. The next two questions are for Judging/Perceiving (questions 6 and 7, 13 and 14, 20 and 21, 27 and 28, etc).

In other words, if we consider the I/E to be dimension 1, the S/N to be dimension 2, the T/F to be dimension 3, and the J/P to be dimension 4, the map of questions to their respective dimensions would look like this (*spaces added for emphasis*):

Notice that there are half as many Introvert/Extrovert questions as there are for the other three dimensions.

Input Data:

The personality data consists of line pairs, one per person. The first line has the person's name, and the second has the person's 70 answers ('A', 'B' or '-'). Notice that the A or B can be either upper or lowercase. A dash represents a question that was skipped by that person, as seen in Han Solo's data below.

Input file personality.txt (partial):

Program Behavior:

Your program's output begins with an introduction of your own creation, such as an explanation of the personality test and/or a fact about your own type. Next your program asks for the input file name to process. You may assume that the user will type a name of a file that exists and can be read. Next the program prompts the user for an output file name; if this file already exists, your program will overwrite its contents. (This is the default PrintStream behavior.)

Log of execution (user input underlined):

```
<< your introduction message here >>
Input file name: personality.txt
Output file name: output.txt
```

Please do not hard-code file names in your code. The input file name used in the above log is personality.txt, but the input file could have other names. You should not place the value "personality.txt" anywhere in your program's code. Similarly, the output file name happens to be named output.txt in the log shown on this page, but this will not always be the case, and your program should not manually use the value "output.txt".

Each pair of lines from the input file is turned into a group of lines in the output file with the name, count of As and Bs for each dimension, % Bs for each dimension (rounded to the nearest percent), and personality type. Questions left blank (indicated by a dash, '--') do not contribute to the count of As/Bs, nor to the percent Bs for that dimension. If the person has the same number of As and Bs for a dimension, give them an "X", as with Han Solo below. Assume that the input file has no errors and that nobody has skipped all questions for a dimension (it would be impossible to determine a percentage in such a case). Reproduce the following output format:

Output file output.txt (partial):

```
Betty Boop
Answers: 1A-9B 17A-3B 18A-2B 18A-2B
Percent B: [90, 15, 10, 10]
Type: ISTJ

Bugs Bunny
Answers: 8A-2B 11A-9B 17A-3B 9A-11B
Percent B: [20, 45, 15, 55]
Type: ESTP

Han Solo
Answers: 2A-8B 9A-9B 11A-9B 15A-5B
Percent B: [80, 50, 45, 25]
Type: IXTJ
```

Implementation Guidelines and Hints:

A major purpose of this assignment is to test your understanding of arrays. Therefore you should use arrays to store the various data for each of the four dimensions of the personality test, and to transform data from one form to another. There are three major transformations you should perform: from the original 70 A/B answers to counts of As and Bs, from counts to percentages of Bs, and from percentages to a four-letter personality type string. These transformations are summarized by the following diagram, using Han Solo's data:

```
\verb|"BA-ABABBB-bbbaababaaaabbaaabbaaabbaBBAAABBABAAABBABAAABBABAAABBABAABBBABAB"|
Answers:
  ₩
           What is computed
                                                Resulting output
            {2, 9, 11, 15}
A count:
B count:
            \{8, 9, 9, 5\}
                                                Answers: 2A-8B 9A-9B 11A-9B 15A-5B
            {80, 50, 45, 25}
B percent:
                                                Percent B: [80, 50, 45, 25]
 Type:
            "IXTJ"
                                                Type: IXTJ
```

Your program should read data a line at a time from the input file using a Scanner object's nextLine method. You must use text processing to analyze the characters representing each person's answers. Each character can be accessed as a char value within the overall line String using the line's charAt method.

The process of converting the 70 answers into counts of As and Bs is one of the most challenging aspects of this program. Pay extra attention to this code to minimize redundancy. If you are having trouble counting the As and Bs, it may help you to print the contents of your arrays. Recall that the method Arrays.toString converts an array to a printable String. For example, to print the contents of an array named counts, you could write the following code:

```
System.out.println("My counts are" + Arrays.toString(counts));
```

You must display percentages of Bs as whole numbers. Recall that Math.round rounds numbers to the nearest integer.

Your program is supposed to produce file output, but it may be easier for you to develop it initially by printing all output to the console. Initially, instead of printing output to a file, consider printing all output to the console, System.out. Then once you have the program logic working, add the file output to your program. See textbook section 6.4 for more information about using PrintStream objects to produce file output.

Stylistic Guidelines:

Use a **class constant** in your program representing the number of dimensions in the test, as an int (with a value of 4). It will not be possible to change this constant and have the program adjust, but it makes the code more readable.

We will grade your method structure very strictly on this assignment. Use at least **four nontrivial methods** besides main. These methods should use parameters and returns, including passing and returning arrays, as appropriate. The methods should be well-structured and avoid redundancy. Chapter 7's Case Study program in textbook section 7.5 is a good example of how to write a larger program with several methods that use arrays as parameters.

Your main method should be a concise summary of the overall program. It is okay for main to contain some code such as println statements, or for main to open files and perform some file I/O. But the main method should not perform too large a share of the overall work itself, such as examining each of the 70 characters of a person's answers to the personality test. Also avoid "chaining," which is when many methods call each other without ever returning to main. For reference, our solution is around 100 lines long and has 5 methods besides main.

We will also check strictly for redundancy on this assignment. If you have a very similar piece of code that is repeated several times in your program, eliminate the redundancy by creating a small helping method and/or by factoring the if/else code as described in section 4.3 of the textbook.

You are limited to features in Chapters 1 through 7. Follow past style guidelines such as indentation, names, variables, types, line lengths, and comments (at the beginning of your program, on each method, and on complex sections of code).
