## RSA Encryption

# Some basic terminology

- Alice wants to send a secret message to Bob
- Eve is eavesdropping
- Cryptographers tell Alice and Bob how to encode their messages
- Cryptanalysts help Eve to break the code
- Historic battle between the cryptographers and the cryptanalysts that continues today

# Start with an Algorithm

Caesar cipher (substitution cipher): ABCDEFGHIJKLMNOPQRSTUVWXYZ GHIJKLMNOPQRSTUVWXYZABCDEF

### Then add a secret key

Both parties know that the secret word is "victory":

ABCDEFGHIJKLMNOPQRSTUVWXYZ

VICTORYABDEFGHJKLMNPQSUWXZ

- "state of the art" for hundreds of years
- Gave birth to cryptanalysis first in the Muslim world, later in Europe

#### Cryptographers vs Cryptanalysts

- A battle that continues today
- Cryptographers try to devise more clever algorithms and keys
- Cryptanalysts search for vulnerabilities
- Early cryptanalysts were linguists:
  - frequency analysis
  - properties of letters

# **Public Key Encryption**

- Proposed by Diffie, Hellman, Merkle
- First big idea: use a function that cannot be reversed (a humpty dumpty function): Alice tells Bob a function to apply using a public key, and Eve can't compute the inverse
- Second big idea: use asymmetric keys (sender and receiver use different keys): Alice has a private key to compute the inverse
- Key benefit: doesn't require the sharing of a secret key

# **RSA Encryption**

- Named for Ron Rivest, Adi Shamir, and Leonard Adleman
- Invented in 1977, still the premier approach
- Based on Fermat's Little Theorem: a<sup>p-1</sup>≡1 (mod p) for prime p, gcd(a, p) = 1
- Slight variation:

 $a^{(p-1)(q-1)} \equiv 1 \pmod{pq}$  for distinct primes p and q, gcd(a,pq) = 1

Requires large primes (100+ digit primes)

## Example of RSA

- Pick two primes p and q, compute  $n = p \times q$
- Pick two numbers e and d, such that: e×d = k(p-1)(q-1) + 1 (for some k)
- Publish n and e (public key), encode with: (original message)<sup>e</sup> mod n
- Keep d, p and q secret (private key), decode with:

(encoded message)<sup>d</sup> mod n

### Why does it work?

 Original message is carried to the e power, then to the d power:

 $(msg^e)^d = msg^{e}^{d}$ 

- Remember how we picked e and d: msg<sup>ed</sup> = msg<sup>k(p-1)(q-1) + 1</sup>
- Apply some simple algebra:
  msg<sup>ed</sup> = (msg<sup>(p-1)(q-1)</sup>)<sup>k</sup> × msg<sup>1</sup>
- Applying Fermat's Little Theorem:
  msg<sup>ed</sup> = (1)<sup>k</sup> × msg<sup>1</sup> = msg

# Politics of Cryptography

- British actually discovered RSA first but kept it secret
- Phil Zimmerman tried to bring cryptography to the masses with PGP and ended up being investigated as an arms dealer by the FBI and a grand jury
- The NSA hires more mathematicians than any other organization

# Exploring further

- Simon Singh, *The Code Book*
- RSA Factoring Challenge (unfortunately the prizes have been withdrawn)
- Shor's algorithm would break RSA if only we had a quantum computer
- Java's BigInteger: isProbablePrime, nextProbablePrime, modPow
