16-1

GREAT IDEAS IN COMPUTER SCIENCE

ANALYSIS OF ALGORITHMIC COMPLEXITY

11/11/2004

(c) 2001-4, University of Washington

16-2

Overview

- Measuring time and space used by algorithms
- Machine-independent measurements
- Costs of operations
- Asymptotic complexity – $O()$ notation and complexity classes
- Comparing algorithms
- Performance tuning

11/11/2004

(c) 2001-4, University of Washington

16-3

Comparing Algorithms

- Example: We'll see two different list implementations
 - Dynamic expanding array
 - Linked list
- We'll see multiple ways of implementing other kinds of collections
- Which implementations are "better"?
- How do we measure?
 - Stopwatch? Why or why not?

11/11/2004

(c) 2001-4, University of Washington

16-4

Program Efficiency & Resources

- Goal: Find way to measure "resource" usage in a way that is independent of particular machines or implementations
- Resources
 - Execution time
 - Execution space
 - Network or disk bandwidth
 - others
- We will focus on execution time
 - Techniques/vocabulary apply to other resource measures

11/11/2004

(c) 2001-4, University of Washington

16-5

Example

- What is the running time of the following method?

```
// Return the sum of the elements in array.
double sum(double[] data) {
    double ans = 0.0;
    for (int k = 0; k < data.length; k++) {
        ans = ans + data[k];
    }
    return ans;
}
```

- How do we analyze this?
- What does the question even mean?

11/11/2004

(c) 2001-4, University of Washington

16-6

Analysis of Execution Time

1. First: describe the *size* of the problem in terms of one or more parameters
 - For the sum method, the size of the data array makes sense
 - Often size of data structure, but can be magnitude of some numeric parameter, etc.
2. Then, count the number of *steps* needed *as a function of the problem size*
 - Need to define what a "step" is
 - First approximation: one simple statement
 - More complex statements will be multiple steps

11/11/2004

(c) 2001-4, University of Washington

16-7

Cost of operations: Constant Time Ops

- Constant-time operations: each take one abstract time "step"
 - Simple variable declaration/initialization (double sum = 0.0;)
 - Assignment of numeric or reference values (var = value;)
 - Arithmetic operation (+, -, *, /, %)
 - Array subscripting (a[index])
 - Simple conditional tests (x < y, p != null)
 - Operator new itself (not including constructor cost)
 - Note: new takes significantly longer than simple arithmetic or assignment, but its cost is independent of the problem we're trying to analyze
- Watch out for things like method calls or constructor invocations that look simple, but can be expensive

11/11/2004

(c) 2001-4, University of Washington

16-8

Cost of operations: Zero-time Ops

- Can sometimes perform operations at compile time
 - Nothing left to do at runtime
- Variable declarations without initialization

```
double[] overdrafts;
```
- Variable declarations with compile-time constant initializers

```
static final int maxButtons = 3;
```
- Some casts (but not those that need a runtime check)

```
int code = (int) '?';
```
- These are generally either ignored or treated as constant-time

11/11/2004

(c) 2001-4, University of Washington

16-9

Sequences of Statements

- Cost of
 $S_1; S_2; \dots; S_n$
is sum of the costs of $S_1 + S_2 + \dots + S_n$

11/11/2004

(c) 2001-4, University of Washington

16-10

Conditional Statement

- We're generally trying to figure out how long it *might* take to execute a statement (*worst case*), so the cost of

```
if (condition) {
    S1;
} else {
    S2;
}
```

is usually the max cost of S1 or S2 plus cost of the condition
- Other possibilities (less common)
 - *Best case* – use the min cost of S1 or S2
 - *Expected (average) case* – probabilistic analysis needed

11/11/2004

(c) 2001-4, University of Washington

16-11

Analyzing Loops

- Basic analysis
 1. Calculate cost of each iteration
 2. Calculate number of iterations
 3. Total cost is the product of these
 - Caution – sometimes need to add up the costs differently if the cost of each iteration is not roughly the same
- Nested loops
 - Total cost is number of iterations of the outer loop times the cost of the inner loop
 - same caution as above

11/11/2004

(c) 2001-4, University of Washington

16-12

Method Calls

- Cost for calling a function is cost of...
 - cost of **evaluating** the arguments (constant or non-constant)
 - + cost of actually **calling** the function (constant overhead)
 - + cost of **passing** each parameter (normally constant time in Java for both numeric and reference values)
 - + cost of **executing** the function body (constant or non-constant?)

```
System.out.println(lineNumber);
System.out.println("Answer is " + calculateResult(x, y*y+42.0));
```

- Note that "evaluating" and "passing" an argument are two different things

11/11/2004

(c) 2001-4, University of Washington

16-13

Exercise

- Analyze the running time of `printMultTable`
 - Pick the problem size
 - Count the number of steps

```
// print multiplication table with
// n rows and columns
void printMultTable(int n) {
    for (int k=1; k <= n; k++) {
        printRow(k, n);
    }
}

// print row r with length n of a
// multiplication table
void printRow(int r, int n) {
    for (int k = 1; k <= n; k++) {
        System.out.print(r*"k + " ");
    }
    System.out.println();
}
```

11/11/2004

(c) 2001-4, University of Washington

16-14

Analysis

11/11/2004

(c) 2001-4, University of Washington

16-15

Comparing Algorithms

- Suppose we analyze two algorithms and get these times (numbers of steps):

- Algorithm 1: $37n + 2n^2 + 120$
- Algorithm 2: $50n + 42$

How do we compare these? What really matters?

- Answer: In the long run, the thing that is most interesting is the cost as the problem size n gets large
- What are the costs for $n=10$, $n=100$; $n=1,000$; $n=1,000,000$?
- Mainstream computers are so fast these days that time needed to solve small problems is rarely of interest
 - Not necessarily so for slow, low-power, or embedded systems

11/11/2004

(c) 2001-4, University of Washington

16-16

Orders of Growth

- What happens as the problem size doubles?

N	$\log_2 N$	$5N$	$N \log_2 N$	N^2	2^N
8	3	40	24	64	256
16	4	80	64	256	65536
32	5	160	160	1024	$\sim 10^9$
64	6	320	384	4096	$\sim 10^{19}$
128	7	640	896	16384	$\sim 10^{38}$
256	8	1280	2048	65536	$\sim 10^{76}$
10000	13	50000	10^5	10^8	$\sim 10^{3010}$

11/11/2004

(c) 2001-4, University of Washington

16-17

Asymptotic Complexity

- Asymptotic: Behavior of complexity function as problem size gets large

- Only thing that really matters is higher-order term
- Can drop low order terms and constants

- The asymptotic complexity gives us a (partial) way to answer "which algorithm is more efficient"

- Algorithm 1: $37n + 2n^2 + 120$ is proportional to n^2
- Algorithm 2: $50n + 42$ is proportional to n

- Graphs of functions are handy tool for comparing asymptotic behavior

11/11/2004

(c) 2001-4, University of Washington

16-18

Big-O Notation

- Definition: If $f(n)$ and $g(n)$ are two complexity functions, we say that
$$f(n) = O(g(n)) \quad (\text{pronounced } f(n) \text{ is } O(g(n)) \text{ or is order } g(n))$$
if there is a constant c such that
$$f(n) \leq c \cdot g(n)$$
for all sufficiently large n

11/11/2004

(c) 2001-4, University of Washington

16-19

Exercise 1

- Prove that $5n+3$ is $O(n)$

11/11/2004

(c) 2001-4, University of Washington

16-20

Exercise 2

- Prove that $5n^2 + 42n + 17$ is $O(n^2)$

11/11/2004

(c) 2001-4, University of Washington

16-21

Implications

- The notation $f(n) = O(g(n))$ is *not* an equality
(yet another abuse of the $=$ sign; c.f., assignment operator)
- Think of it as shorthand for
 - “ $f(n)$ grows at most like $g(n)$ ” or
 - “ f grows no faster than g ” or
 - “ f is bounded by g ”
- $O()$ notation is a *worst-case* analysis
 - Generally useful in practice
 - Sometimes want *average-case* or *expected-time* analysis if worst-case behavior is not typical (but often harder to analyze)

11/11/2004

(c) 2001-4, University of Washington

16-22

Complexity Classes

- Several common complexity classes (problem size n)
 - Constant time: $O(k)$ or $O(1)$
 - Logarithmic time: $O(\log n)$ [Base doesn't matter. Why?]
 - Linear time: $O(n)$
 - “ $n \log n$ ” time: $O(n \log n)$
 - Quadratic time: $O(n^2)$
 - Cubic time: $O(n^3)$
 - ...
 - Exponential time: $O(k^n)$
- $O(n^k)$ is often called *polynomial time*

11/11/2004

(c) 2001-4, University of Washington

16-23

Big-O Arithmetic

- For most common functions, comparison can be enormously simplified with a few simple rules of thumb
- Memorize complexity classes in order from smallest to largest: $O(1)$, $O(\log n)$, $O(n)$, $O(n \log n)$, $O(n^2)$, etc.
- Ignore constant factors
$$300n + 5n^4 + 6 + 2^n = O(n + n^4 + 2^n)$$
- Ignore all but highest order term
$$O(n + n^4 + 2^n) = O(2^n)$$

11/11/2004

(c) 2001-4, University of Washington

16-24

Rule of Thumb

- If the algorithm has **polynomial** time or better: **practical**
 - typical pattern: examining all data, a fixed number of times
- If the algorithm has **exponential** time: **impractical**
 - typical pattern: examine *all combinations* of data
- What to do if the algorithm is exponential?
 - Try to find a different algorithm
 - Some problems can be proved not to have a polynomial solution
 - Other problems don't have known polynomial solutions, despite years of study and effort
 - Sometimes you settle for an approximation
 - The correct answer most of the time, or an almost-correct answer all of the time

11/11/2004

(c) 2001-4, University of Washington

16-25

Computer Science Note

- Algorithmic complexity theory is one of the key intellectual contributions of Computer Science
- Typical problems
 - What is the worst/average/best-case performance of an algorithm?
 - What is the best complexity bound for all algorithms that solve a particular problem? (i.e., how intrinsically difficult is the problem – regardless of how clever a programmer you are?)
- Interesting and (in many cases) complex, sophisticated math
 - Probabilistic and statistical as well as discrete
- Still some key open problems
 - Most notorious: P ?= NP

11/11/2004

(c) 2001-4, University of Washington

16-26

Analyzing List Operations (1)

- We can use $O()$ notation to compare the costs of different list implementations
- Operation Dynamic Array Linked List
 - Construct empty list
 - Size of the list
 - isEmpty
 - clear

11/11/2004

(c) 2001-4, University of Washington

16-27

Analyzing List Operations (2)

- | Operation | Dynamic Array | Linked List |
|---|---------------|-------------|
| • Add item to end of list | | |
| • Locate item (contains, indexOf) | | |
| • Add or remove item once it has been located | | |

11/11/2004

(c) 2001-4, University of Washington

16-28

Wait! Isn't this totally bogus??

- Write better code!!
 - More clever hacking in the inner loops (assembly language, special-purpose hardware in extreme cases)
- Moore's law: Speeds double every 18 months
 - Wait and buy a faster computer in a year or two!

- But ...

11/11/2004

(c) 2001-4, University of Washington

16-29

How long is a Computer-Day?

- If a program needs $f(n)$ microseconds to solve some problem, how big a problem can it solve in a day?

• One day = $1,000,000 \times 24 \times 60 \times 60 = 9 \times 10^{10}$ (approx)

$f(n)$ n such that $f(n) = \text{one day}$

n 9×10^{10}

$5n$ 2×10^{10}

$n \log_2 n$ 3×10^9

n^2 3×10^5

n^3 4×10^3

2^n 36

11/11/2004

(c) 2001-4, University of Washington

16-30

Speed Up The Computer by 1,000,000

- Suppose technology advances so that a future computer is 1,000,000 fast than today's

(Or you discover a clever hack that gives a 1,000,000 speedup)

$f(n)$	original n	speedup on future machine
n	$9 * 10^{10}$	million times
$5n$	$2 * 10^{10}$	million times
$n \log_2 n$	$3 * 10^9$	60,000 times
n^2	$3 * 10^5$	1,000 times
n^3	$4 * 10^3$	100 times
2^n	36	+20

11/11/2004

(c) 2001-4, University of Washington

16-31

Practical Advice For Speed Lovers

- First pick the right algorithm and data structure
 - Implement it clearly and carefully, insuring correctness
- Then optimize for speed – but only where it matters
 - Constants do matter in the real world
 - Clever coding can speed things up, but the result is likely to be harder to read, modify
 - Use tools to find hotspots – concentrate on these

"Premature optimization is the root of all evil"

– Donald Knuth

11/11/2004

(c) 2001-4, University of Washington

16-32

More Advice...

"It is easier to make a correct program efficient than to make an efficient program correct"

-- Edsger Dijkstra

11/11/2004

(c) 2001-4, University of Washington

16-33

Summary

- Analyze algorithm sufficiently to determine complexity
- Compare algorithms by comparing asymptotic complexity
- For large problems, an asymptotically faster algorithm will always trump clever coding tricks
- Optimize/tune only things that actually matter, once you've picked the best algorithm

11/11/2004

(c) 2001-4, University of Washington

16-34
