

CSE 143 Java

Sorting

Reading: Sec. 19.3

11/21/2004

(c) 2001-4, University of Washington

23-1

Sorting

- Binary search is a huge speedup over sequential search
 - But requires the list be sorted
- Slight Problem: How do we get a sorted list?
 - Maintain the list in sorted order as each word is added
 - Sort the entire list when needed
- Many, many algorithms for sorting have been invented and analyzed
- Our algorithms mostly assume the data is already in an array
 - Other starting points and assumptions are possible

11/21/2004

(c) 2001-4, University of Washington

23-2

Insert for a Sorted List

- One possibility: ensure the list is always sorted as it is created
- Exercise: Assume that words[0..size-1] is sorted. Place new word in correct location so modified list remains sorted
 - Assume that there is spare capacity for the new word
- Before coding:
 - Draw pictures of an example situation, before and after
 - Write down the postconditions for the operation

```
// given existing list words[0..size-1], insert word in correct place and increase size  
void insertWord(String word) {
```

```
    size++;  
}
```

11/21/2004

23-3

Picture

- Draw your picture here

11/21/2004

(c) 2001-4, University of Washington

23-4

Insertion Sort

- Once we have insertWord working...
- We can sort a list in place by repeating the insertion operation

```
void insertionSort() {  
    int finalSize = size;  
    size = 1;  
    for (int k = 1; k < finalSize; k++) {  
        insertWord(words[k]);  
    }  
}
```

11/21/2004

(c) 2001-4, University of Washington

23-5

Insertion Sort As A Card Game Operation

- A bit like sorting a hand full of cards dealt one by one:
 - Pick up 1st card – it's sorted, the hand is sorted
 - Pick up 2nd card; *insert* it after or before 1st – both sorted
 - Pick up 3rd card; *insert* it after, between, or before 1st two
 - ...
- Each time:
 - Determine where new card goes
 - Make room for the newly inserted card and place it there

11/21/2004

(c) 2001-4, University of Washington

23-6

Insertion Sort As Invariant Progression

11/21/2004

(c) 2001-4, University of Washington

23-7

Insertion Sort

```
// instance variable
int[] list;           // list[0..size-1] is the list to be sorted
int size;
// Sort list[0..size-1]
public void sort {
  for (int j=1; j < size; j++) {
    // pre: 1 <= j && j < size && list[0 ... j-1] is in sorted order
    int temp = list[j];
    for (int i = j-1; i >= 0 && list[i] > temp; i--) {
      list[i+1] = list[i];
    }
    list[j+1] = temp;
    // post: 1 <= j && j < size && list[0 ... j] in sorted order
  }
}
```

11/21/2004

(c) 2001-4, University of Washington

23-8

Insertion Sort Trace

Initial array contents

- 0 pear
- 1 orange
- 2 apple
- 3 rutabaga
- 4 aardvark
- 5 cherry
- 6 banana
- 7 kumquat

11/21/2004

(c) 2001-4, University of Washington

23-9

Insertion Sort Performance

- Cost of each insertWord operation:
- Number of times insertWord is executed:
- Total cost:
- Can we do better?

11/21/2004

(c) 2001-4, University of Washington

23-10

Analysis

- Why was binary search so much more effective than sequential search?
 - Answer: binary search divided the search space in half each time; sequential search only reduced the search space by 1 item per iteration
- Why is insertion sort $O(n^2)$?
 - Each insert operation only gets 1 more item in place at cost $O(n)$
 - $O(n)$ insert operations
- Can we do something similar for sorting?

11/21/2004

(c) 2001-4, University of Washington

23-11

Where are we on the chart?

N	$\log_2 N$	5N	$N \log_2 N$	N^2	2^N
8	3	40	24	64	256
16	4	80	64	256	65536
32	5	160	160	1024	$\sim 10^9$
64	6	320	384	4096	$\sim 10^{19}$
128	7	640	896	16384	$\sim 10^{38}$
256	8	1280	2048	65536	$\sim 10^{76}$
10000	13	50000	10^5	10^8	$\sim 10^{3010}$

11/21/2004

(c) 2001-4, University of Washington

23-12

Divide and Conquer Sorting

- Idea: emulate binary search in some ways
 1. divide the sorting problem into two subproblems;
 2. recursively sort each subproblem;
 3. combine results
- Want division and combination at the end to be fast
- Want to be able to sort two halves independently
- This algorithm strategy is called *divide and conquer*

11/21/2004

(c) 2001-4, University of Washington

23-13

Quicksort

- Invented by C. A. R. Hoare (1962)
- Idea
 - Pick an element of the list: the *pivot*
 - Place all elements of the list smaller than the pivot in the half of the list to its left; place larger elements to the right
 - Recursively sort each of the halves
- Before looking at any code, see if you can draw pictures based just on the first two steps of the description

11/21/2004

(c) 2001-4, University of Washington

23-14

Code for QuickSort

```
// Sort words[0..size-1]
void quickSort() {
    qsort(0, size-1);
}

// Sort words[lo..hi]
void qsort(int lo, int hi) {
    // quit if empty partition
    if (lo > hi) { return; }
    int pivotLocation = partition(lo, hi); // partition array and return pivot loc
    qsort(lo, pivotLocation-1);
    qsort(pivotLocation+1, hi);
}
```

11/21/2004

(c) 2001-4, University of Washington

23-15

Recursion Analysis

- Base case? Yes.

```
// quit if empty partition
if (lo > hi) { return; }
```
- Recursive cases? Yes

```
qsort(lo, pivotLocation-1);
qsort(pivotLocation+1, hi);
```

 - Each recursive cases work on a smaller subproblem, so algorithm will terminate

11/21/2004

(c) 2001-4, University of Washington

23-16

A Small Matter of Programming

- *Partition* algorithm
 - Pick pivot
 - Rearrange array so all smaller element are to the left, all larger to the right, with pivot in the middle
- *Partition* is not recursive
- Fact of life: *partition* can be tricky to get right
 - Pictures and invariants are your friends here
- How do we pick the pivot?
 - For now, keep it simple – use the first item in the interval
 - Better strategies exist

11/21/2004

(c) 2001-4, University of Washington

23-17

Partition design

- We need to partition words[lo..hi]
- Pick words[lo] as the pivot
- Picture:

11/21/2004

(c) 2001-4, University of Washington

23-18

A Partition Implementation

- Use first element of array section as the pivot
- Invariant:

11/21/2004

(c) 2001-4, University of Washington

23-19

Partition Algorithm: PseudoCode

```
// Partition words[lo..hi]; return location of pivot in range lo..hi
int partition(int lo, int hi) {

}
}
```

11/21/2004

(c) 2001-4, University of Washington

23-20

Partition Test

- Check: partition(0,7)

0 orange
1 pear
2 apple
3 rutabaga
4 aardvark
5 cherry
6 banana
7 kumquat

11/21/2004

(c) 2001-4, University of Washington

23-21

Complexity of QuickSort

- Each call to QuickSort (ignoring recursive calls):
 - Each call of partition() is $O(n)$ where n is size of the *part* of array being sorted
 - Note: This n is smaller than the N of the original problem
 - Some $O(1)$ work
 - Total = $O(n)$ (n is the size of array part being sorted)
- Including recursive calls:
 - Two recursive calls at each level of recursion, each partitions "half" the array at a cost of $O(n/2)$
 - How many levels of recursion?

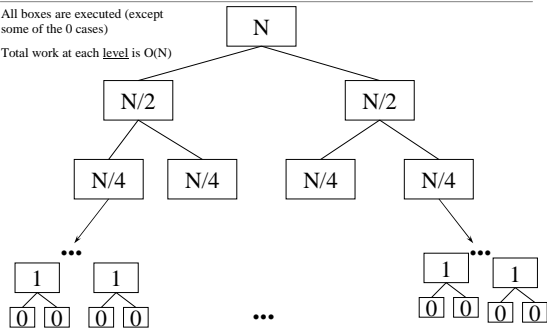

11/21/2004

(c) 2001-4, University of Washington

23-22

QuickSort (Ideally)

All boxes are executed (except some of the 0 cases)
Total work at each level is $O(N)$

11/21/2004

(c) 2001-4, University of Washington

23-23

QuickSort Performance (Ideal Case)

- Each partition divides the list parts in half
 - Sublist sizes on recursive calls: $n, n/2, n/4, n/8, \dots$
 - Total depth of recursion: _____
 - Total work at each level: $O(n)$
 - Total cost of quicksort: _____ !

- For a list of 10,000 items
 - Insertion sort: $O(n^2)$: 100,000,000
 - Quicksort: $O(n \log n)$: $10,000 \log_2 10,000 = 132,877$

11/21/2004

(c) 2001-4, University of Washington

23-24

Worst Case for QuickSort

- If we're very unlucky, then each pass through partition removes only a *single* element.

- In this case, we have N levels of recursion rather than $\log_2 N$. What's the total complexity?

11/21/2004

(c) 2001-4, University of Washington

23-25

QuickSort Performance (Worst Case)

- Each partition manages to pick the largest or smallest item in the list as a pivot
 - Sublist sizes on recursive calls:
 - Total depth of recursion: _____
 - Total work at each level: $O(n)$
 - Total cost of quicksort: _____ !

11/21/2004

(c) 2001-4, University of Washington

23-26

Worst Case vs Average Case

- QuickSort has been shown to work well in the average case (mathematically speaking)
- In practice, QuickSort works well, provided the pivot is picked with some care
- Some strategies for choosing the pivot:
 - Compare a small number of list items (3-5) and pick the *median* for the pivot
(Typically check the first, middle, last, and a couple of items in between – works well even if the original array is almost sorted)
 - Pick a pivot element *randomly* (!) in the range $lo..hi$

11/21/2004

(c) 2001-4, University of Washington

23-27

QuickSort as an Instance of Divide and Conquer

Generic Divide and Conquer	QuickSort
1. Divide	Pick an element of the list: the <i>pivot</i> Place all elements of the list smaller than the pivot in the half of the list to its left; place larger elements to the right
2. Solve subproblems separately (and recursively)	Recursively sort each of the halves
3. Combine subsolutions to get overall solution	Surprise! Nothing to do

11/21/2004

(c) 2001-4, University of Washington

23-28

Another Divide-and-Conquer Sort: Mergesort

- Split array in half
 - just take the first half and the second half of the array, *without* rearranging
- Sort the halves separately
- Combining the sorted halves ("merge")
 - repeatedly pick the least element from each array
 - compare, and put the smaller in the resulting array
 - example: if the two arrays are

1	12	15	20	
5	6	13	21	30

 The "merged" array is

1	5	6	12	13	15	20	21	30
---	---	---	----	----	----	----	----	----
 - note: we will need a second array to hold the result

11/21/2004

(c) 2001-4, University of Washington

23-29

Quicksort vs MergeSort

- Mergesort always has subproblems of size $n/2$
 - Which means guaranteed $O(n \log n)$
- But mergesort requires an extra array for the result
 - No problem if you're sorting disk or tape files
 - Can be a problem if you're trying to sort large lists in main memory
- In practice, quicksort is the most commonly used general-purpose sort
 - Pretty easy to pick pivots well, so expected time is $O(n \log n)$
 - Doesn't require extra space for a copy of the data

11/21/2004

(c) 2001-4, University of Washington

23-30

Summary

- **Divide and Conquer**
 - Algorithm design strategy that exploits recursion
 - Divide original problem into subproblems
 - Solve each subproblem recursively
 - Can sometimes yield dramatic performance improvements
- **Sorting**
 - Quicksort, mergesort: classic divide and conquer algorithms
