

CSE 143

Streams

Reading: Ch. 16

2/3/2005

(c) 2001-5, University of Washington

12-1

Overview

- Topics
 - Streams – communicating with the outside world
 - Basic Java files
 - Other stream classes

2/3/2005

(c) 2001-5, University of Washington

12-2

Input and Output

- Communicating with the outside world

2/3/2005

(c) 2001-5, University of Washington

12-3

Streams

- Java model of communication: streams
 - Sequence of data flowing from a source to a program, or from a program to a destination (sink)
 - Files are common sources and sinks
 - Others: network sockets, interprogram communication, ...

2/3/2005

(c) 2001-5, University of Washington

12-4

Stream after Stream...

- Stream are a useful model for processing data along the way, in a pipeline

2/3/2005

(c) 2001-5, University of Washington

12-5

Other Possible Kinds of Stream Converters

- Compression
- Encryption
- Filtering
- Translation
- Statistics gathering
- Security monitoring
- Routing/Merging
- Reducing Bandwidth (Size & Detail), e.g. of graphics or sound
 - "lossy compression" – JPEG, MP3, many others
- Noise reduction, image sharpening, ...
- Many, many more...

2/3/2005

(c) 2001-5, University of Washington

12-6

Streams vs. Files

- Many languages don't make clear distinction
- In Java:
 - "file" is the collection of data, managed by the operating system
 - "stream" is a flow of data from one place to another
- A stream is an abstraction for data flowing from or to a file, remote computer, URL, hardware device, etc.

2/3/2005

(c) 2001-5, University of Washington

12-7

Java Stream Library

- Huge variety of stream classes in java.io.*
 - Some are data sources or sinks
 - Others are converters that take data from a stream and transform it somehow to produce a stream with different characteristics
- Highly modular
 - Lots of different implementations all sharing a common interface; can be mixed and matched and chained easily
 - Great OO design example, in principle
 - In practice, it can be very confusing (simple I/O is messy)
(improved simple I/O in Java 1.5 – printf method, Scanner class)

2/3/2005

(c) 2001-5, University of Washington

12-8

Common Stream Processing Pattern

- Basic idea the same for input & output

```
// input                // output
open a stream           open a stream
while more data {      while more data {
  read & process next data  write data to stream
}
close stream           close stream
```

2/3/2005

(c) 2001-5, University of Washington

12-9

Opening & Closing Streams

- Before a stream can be used it must be *opened*
 - Create a stream object and connect it to source or destination of the stream data
 - Often done implicitly as part of creating stream objects
- When we're done with a stream, it should be *closed*
 - Takes care of any unfinished operations, then breaks the connection between the program and the data source/destination

2/3/2005

(c) 2001-5, University of Washington

12-10

Java Streams

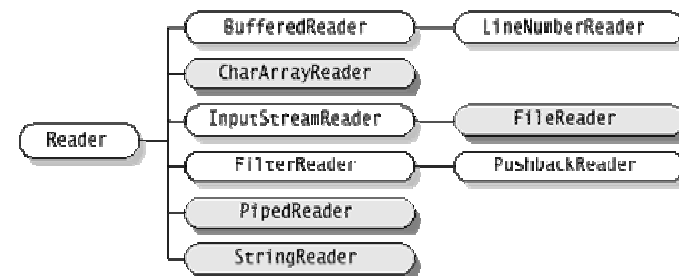

- 2 major families of stream classes
- **Byte streams** – read/write **byte** values
 - Corresponds to physical data – network and disk I/O streams
 - Abstract classes: InputStream and OutputStream
- **Character streams** – read/write **char** values
 - Added in Java 1.1
 - Primary (Unicode) text input/output stream classes
 - Abstract classes: Reader and Writer
 - Footnote: System.in and System.out should be character streams, but are byte streams for historical reasons (existed before Java 1.1, when character streams were added, and remain unchanged to preserve backward compatibility)

2/3/2005

(c) 2001-5, University of Washington

12-11

Character Input Streams

2/3/2005

(c) 2001-5, University of Washington

12-12

Byte Output Streams

2/3/2005

(c) 2001-5, University of Washington

12-13

Streams and Exceptions

- Many operations can throw IOException
 - All input operations, in particular
- Normally throws a specific subclass of IOException
 - depending on the actual error
- IOException is “checked”
 - (Review question: what does a “checked” exception imply?)

2/3/2005

(c) 2001-5, University of Washington

12-14

Basic Reader/Writer Operations

• Reader

```
int read();           // return Unicode value of next character;
                    // return -1 if end-of-stream
int read(char[] cbuf); // read several characters into array;
                    // return -1 if end-of-stream
void close();        // close the stream
```

• Writer

```
void write(int c);   // write character whose Unicode value is c
void write(char[] cbuf); // write array contents
void write(String s); // write string
void close();        // close the stream
```

- To convert Unicode int to char, or vice versa: use a cast

2/3/2005

(c) 2001-5, University of Washington

12-15

File Readers and Writers

- To read a (Unicode) text file (not a binary data file), instantiate FileReader
 - A subclass of Reader: implements read and close operations
 - Constructors take a File object or a string with the name of the file to open and read from
- To write to a text file, instantiate FileWriter
 - A subclass of Writer: implements write and close operations
 - Constructors take a File object or the name of the file to open/create and overwrite (can also append to an existing file using a different constructor)

2/3/2005

(c) 2001-5, University of Washington

12-16

Text Files vs Char Data

- Most of the world's text files use 8-bit characters
 - ASCII and variations of ASCII
 - Internal to Java, char data is *always* 2-byte Unicode
 - Java Reader deals only with Unicode
- Big problem: how to read and write normal (ASCII) text files in Java?
- Solution: stream classes which adapts 8-bit chars to Unicode
 - Generally taken care of automatically – normally don't need to worry about the distinction

2/3/2005

(c) 2001-5, University of Washington

12-17

Copy a Text File, One Character at a Time

```
public void copyFile(String sourceFilename, String destFilename)
    throws IOException {
    FileReader inFile = new FileReader(sourceFilename);
    FileWriter outFile = new FileWriter(destFilename);
    int ch = inFile.read();
    while (ch != -1) {
        outFile.write(ch);
        System.out.println("The next char is \" + (char)ch + "\"; // why !' ?
        ch = inFile.read();
    }
    inFile.close();
    outFile.close();
}
```

2/3/2005

(c) 2001-5, University of Washington

12-18

Interlude: Where is the File?

- In the previous slide, we opened the files with

```
FileReader inFile = new FileReader(sourceFilename);
FileWriter outFile = new FileWriter(destFilename);
```
- The file names could be complete paths like "c:\Documents and Settings\J User\story.txt", but...
 - Not portable – different operating systems have different file naming conventions
 - Not convenient – what if we move the document?
- Would like to be able to use a name like "story.txt" to open the file
 - But if we do, where should we put the file?

2/3/2005

(c) 2001-5, University of Washington

12-19

File Directories

- When we use a simple file name

```
FileReader inFile = new FileReader("story.txt");
```

Java looks for that file in the "current directory"
- Current directory
 - If the program is executed from a command-line prompt, it is the current directory when the "java" command is entered
 - If it is executed by other development tools, it may well be something different
 - Is there a portable scheme way to find the file, assuming it's in the same directory or jar file as the main program .class file?
 - Yes – but you might not really want to have to know the details

2/3/2005

(c) 2001-5, University of Washington

12-20

Finding Files (optional)

- The industrial-strength solution is to use a class loader method that will search all directories it knows about
 - Includes the directory or jar file containing the program's .class files, Java standard libraries, any additional libraries on the *classpath*, etc.
- Ready?

```
URL url = getClass().getClassLoader().getResource(fileName);
```

 - If url!=null, then it can be used to open the file (also works for other resources like images and icons)
 - No, this won't be on the test

2/3/2005

(c) 2001-5, University of Washington

12-21

Opening Files Using File Dialogs

- Easy, portable solution for our purposes is JFileDialog
- Lots (tons) of options, but basic use is quite simple

```
JFileChooser chooser = new JFileChooser();
int result1 = chooser.showOpenDialog(null);
File inFile = chooser.getSelectedFile();
System.out.println("Input file selected is " + inFile);
int result2 = chooser.showSaveDialog(null);
File outFile = chooser.getSelectedFile();
System.out.println("Output file selected is " + outFile);
```

- The int results of the show...Dialog methods indicate whether the dialog was dismissed with ok, cancel, or something else
 - Should check this before using the selected file info

2/3/2005

(c) 2001-5, University of Washington

12-22

More Efficient I/O – BufferedReader/Writer

- Can improve efficiency by reading/writing many characters at a time
- **BufferedReader**: a converter stream that performs this chunking
 - **BufferedReader** constructor takes any kind of Reader as an argument -- can make any read stream buffered
 - **BufferedReader** supports standard Reader operations -- clients don't have to change to benefit from buffering
 - **Key addition**: provides a portable `readLine()`

```
String readLine(); // return an entire line of input; or null if
// end-of-stream reached
```

[handles the complexities of how end-of-line is represented on different systems]

2/3/2005

(c) 2001-5, University of Washington

12-23

BufferedWriter

- **BufferedWriter**: a converter stream that performs chunking on writes
 - **BufferedWriter** constructor takes any kind of Writer as an argument
 - **BufferedWriter** supports standard Writer operations
 - **Also supports** `newLine()`

```
void newLine(); // write an end-of-line character
[As with readLine, does the appropriate thing for the local system's convention
for how end-of-line is actually represented]
```

2/3/2005

(c) 2001-5, University of Washington

12-24

Copy a Text File, One *Line* at a Time

```
public void copyFile(File sourceFile, File destFile)
    throws IOException {
    BufferedReader inFile = new BufferedReader(new FileReader(sourceFile));
    BufferedWriter outFile = new BufferedWriter(new FileWriter(destFile));
    String line = inFile.readLine();
    while (line != null) {
        outFile.write(line);
        outFile.newLine();
        System.out.println("The next line is \"" + line + "\"");
        line = inFile.readLine();
    }
    inFile.close();
    outFile.close();
}
```

2/3/2005

(c) 2001-5, University of Washington

12-25

PrintWriter

- **PrintWriter** is another converter for a write stream
 - Adds `print` & `println` methods for primitive types, strings, objects, etc., just as we've used for `System.out`
 - Does not throw exceptions (to make it more convenient to use)
 - Optional 2nd boolean parameter in constructor to request output be flushed (force all output to actually appear) after each `println`
 - Useful for interactive consoles where messages need to appear right away

2/3/2005

(c) 2001-5, University of Washington

12-26

Copy a Text File, Using **PrintWriter**

```
public void copyFile(File srcFile, File destFile)
    throws IOException {
    BufferedReader inFile = new BufferedReader(new FileReader(srcFile));
    PrintWriter outFile =
        new PrintWriter(new BufferedWriter(new FileWriter(destFile)));
    String line = inFile.readLine();
    while (line != null) {
        outFile.println(line);
        System.out.println("The next line is \"" + line + "\"");
        line = inFile.readLine();
    }
    inFile.close();
    outFile.close();
}
```

2/3/2005

(c) 2001-5, University of Washington

12-27

StringReader and StringWriter

- **Strings as streams(!)**
- **StringReader**: construct character stream from a **String**
 - `StringReader inStream = new StringReader("the source");`
 - // could now copy inStream to a file, or somewhere else*
- **StringWriter**: write stream to a **String**
 - `StringWriter outStream = new StringWriter();`
 - // now write onto outStream, using outStream.write(...), outStream.print(...), etc.*
 - `String theResult = outStream.toString();`

2/3/2005

(c) 2001-5, University of Washington

12-28

Binary Streams

- For processing binary data (encoded characters, executable programs, other low-level data), use `InputStreams` and `OutputStreams`
- Operations are similar to `Reader` and `Writer` operations
 - Replace `char` with `byte` in `read`; no `write(String)`
- Many analogous classes to `Readers` and `Writers`:
 - `FileInputStream`, `FileOutputStream`
 - `BufferedInputStream`, `BufferedOutputStream`
 - `ByteArrayInputStream`, `ByteArrayOutputStream`
 - `ObjectInputStream`, `ObjectOutputStream` -- read & write whole objects!

2/3/2005

(c) 2001-5, University of Washington

12-29

Conversion from Binary to Text Streams

- `InputStreamReader`: creates a `Reader` from an `InputStream`

```
// System.in is of type InputStream
Reader inStream = new InputStreamReader(System.in);
// now can treat it nicely as a character stream
```

- `OutputStreamWriter`: creates a `Writer` from an `OutputStream`

```
// System.out is of type OutputStream
Writer outStream = new OutputStreamWriter(System.out);
// now can treat it nicely as a character stream
```

2/3/2005

(c) 2001-5, University of Washington

12-30

Network Streams

- Import `java.net.*`
- Use `URL` to create a name of something on the web
- Use `openStream()` method to get a `InputStream` on the contents of the `URL`

```
URL url = new URL("http://www.cs.washington.edu/index.html");
InputStream inStream = url.openStream();
... // now read from inStream
```
- Use `openConnection()` and `URLConnection` methods to get more control

```
URLConnection connection = url.openConnection();
OutputStream outStream = connection.getOutputStream();
... // now write to outStream (assuming target url allows writing!)
```
- `Socket` class for even more flexible network reading & writing
 - But lower-level; program has to take care of more details

2/3/2005

(c) 2001-5, University of Washington

12-31

Summary

- Java stream libraries
 - Comprehensive, flexible, easy to compose multiple streams in a chain
 - But not simple to do simple things
- What to take away
 - `BufferedReader` and `readLine()` for text input
 - `PrintWriter` and `print()/println()` for text output
 - `JFileChooser` to select files when opening
 - `close()` when done
- The rest should give you pointers to things to learn when you need them

2/3/2005

(c) 2001-5, University of Washington

12-32
