CSE 143 Java

Collections

Reading: Ch. 12 (mostly review)

Collections

- Most programs need to store and access collections of data
- Collections are worth studying because...
  - They are widely useful in programming
  - They provide examples of the OO approach to design and implementation
    - identify common pattern
    - regularize interface to increase commonality
    - factor them out into common interfaces, abstract classes
  - Their implementation will raise issues previously swept under the rug, particularly efficiency

Goals for Next Several Lectures

- Survey different kinds of collections, focusing on their *interfaces*
  - Lists, sets, maps
  - Iterators over collections
- Then look at different possible *implementations*
  - Arrays, linked lists, hash tables, trees
  - Mix-and-match implementations to interfaces
- Compare implementations for efficiency
  - How do we measure efficiency?
  - Implementation tradeoffs

Java 2 Collection Interfaces

- Key interfaces in Java 1.2 and later:
  - Collection – a collection of objects
  - List extends Collection – ordered sequence of objects (first, second, third, ...); duplicates allowed
  - Set extends Collection – unordered collection of objects; duplicates suppressed
  - Map – collection of <key, value> pairs; each key may appear only once in the collection; item lookup is via key values*
    (Think of pairs like <word, definition>, <id#, student record>, <book ISBN number, book catalog description>, etc.)
    *technically not an extension of Collection, but interface is generally similar
  - Iterator – provides element-by-element access to items in a collection

Java 2 Collection Implementations

- Main concrete implementations of these interfaces:
  - ArrayList implements List (using arrays)
  - LinkedList implements List (using linked lists)
  - HashSet implements Set (using hash tables)
  - TreeSet implements Set (using trees)
  - HashMap implements Map (using hash tables)
  - TreeMap implements Map (using trees)

Footnote: Pre-Java 2 Collections

- Java 1.0 and 1.1 had different collection classes
  - still retained because they are used in existing (old) code
- Correspondence of some classes and interfaces:

Java 1.2	Java 1.0, 1.1
ArrayList	Vector
Map	Dictionary
HashMap	HashTable
Iterator	Enumeration

- Newer classes generally lighter weight, more efficient, but very similar interfaces
- *Use the new classes* unless you have a specific reason to use the old ones

interface Collection

- Basic methods available on most collections:
  - int size( ) – # of items currently in the collection
  - boolean isEmpty( ) – (size( ) == 0)
  - boolean contains(Object o) – true if o is in the collection
    - [how to compare o with the elements already in the collection?]
  - boolean add(Object o) – ensure that o is in the collection, possibly adding it; return true if collection altered; false if not. [leaves a lot unspecified….]
  - boolean addAll(Collection other) – add all elements in the other collection
  - boolean remove(Object o) – remove one o from the collection, if present; return true if something was actually removed
  - void clear( ) – remove all elements
  - Iterator iterator( ) – return an iterator object for this collection
- Note: much richer interface than an array

interface Iterator

- Provides access to elements of any collection one-by-one, even if the collection has no natural ordering (sets, maps are not ordered)
- Interface
  - boolean hasNext( ) – true if the iteration has more elements
  - Object next( ) – next element in the iteration; precondition: hasNext( ) == true
  - void remove( ) – remove from the underlying collection the element last returned by the iteration. [Optional; some collections don't support this.]

Standard Iterator Loop Pattern

```
Collection c = ...;
Iterator iter = c.iterator( );
while (iter.hasNext( )) {
  Object elem = iter.next( );   // might want cast to specific type
  ...  // do something with elem
}
```

- Note similarity to generic file/stream processing loop:

```
open stream -- perhaps from file
while not at end of stream {
  read/write next data item, do something with it
}
```

Iterators vs. Counter Loops

- A related pattern is the *counting loop*:

```
ArrayList list = ...;
for (int i = 0; i < list.size( ); i ++) {
    Object elem = list.get(i);
    ...  // do something with elem
}
```

- The iterator pattern is generally preferable because it...
  - works for any collection, even those without a get(int) operation
  - encapsulates the tedious details of iterating, indexing
  - is efficient – get(i) is not fast in some collections, even if available
- CSE143 style rule: use iterator pattern
  - Unless there are compelling reasons to use a counting loop

Collection Contents: Objects

- All Java Collections store Objects
- Cannot store primitive types directly
  - Use wrapper classes if needed
- Values returned from Collections must be cast back to a type

```
Integer age = new Integer(21);
ArrayList ageList = new ArrayList( );
ageList.add(0, age);
Integer ageAgain = ageList.get(0);          // type error!
Object ageAgain = ageList.get(0);           // correct – but not always useful!
Integer ageAgain = (Integer) ageList.get(0);  // correct and useful
```

- Contrast: Arrays are declared with a single, specific element type
  - Could be any type: Object, primitive type, interface, abstract class, concrete class, another array, etc.

Lists as Collections

- In some collections, there is no natural order
  - Toys in a toybox, grocery items in a bag, grains of sand on the beach
- In other collections, the order of elements is natural and important
  - Chapters of a book, floors in a building, people camping out to buy *Star Wars* tickets
- Lists are collections where the elements have an order
  - Each element has a definite position (first, second, third, ...)
  - positions are generally numbered from 0

interface List extends Collection

- Following are included in all Java Lists (and some other Collection types):
  - Object get(int pos) – return element at position pos
  - boolean set(int pos, Object elem) – store elem at position pos
  - boolean add(int pos, Object elem) – store elem at position pos; slide elements at position pos to size( )-1 up one position to the right
  - Object remove(int pos) – remove item at given position; shift remaining elements to the left to fill the gap; return the removed element
  - int indexOf(Object o) – return position of first occurrence of o in the list, or -1 if not found
- Precondition for most of these is 0 <= pos < size( )

interface ListIterator extends Iterator

- The iterator( ) method for a List actually returns an instance of ListIterator (extends Iterator)
  - Can also use listIterator(int pos) to get a ListIterator starting at the given position in the list
- ListIterator returns objects in the list collection in the order they appear in the collection
- Supports additional methods:
  - hasPrevious( ), previous( ) – for iterating backwards through a list
  - set(Object o) – to replace the current element with something else
  - add(Object o) – to insert an element after the current element

List Implementations

- ArrayList – internal data structure is an array
  - Fast iterating
  - Fast access to individual elements (get(int), set(int, Object))
  - Slow add/remove except at the end of the list
- LinkedList – internal data structure is a linked list
  - Fast iterating
  - Slow access to individual elements (get(int), set(int, Object))
  - Fast add/remove, even in the middle of the list
- We'll dissect both forms of implementation shortly

interface Set extends Collection

- As in math, a Set is an unordered collection, with no duplicate elements
  - attempting to add an element already in the set does not change the set
- Interface is same as Collection, but refines the specifications
  - The specs are in the form of comments
- interface SortedSet extends Set
  - Same as Set, but iterators always return set elements in order
  - Requires that elements be Comparable: implement the compareTo(Object) method, returning a negative, 0, or positive number to mean <=, ==, or >=, respectively

interface Map

- Collections of <key, value> pairs
  - keys are unique, but values need not be
- Doesn't extend Collection, but does provide similar methods
  - size( ), isEmpty( ), clear( )
- Basic methods for dealing with <key, value> pairs:
  - Object put(Object key, Object value) – add <key, value> to the map, replacing the previous <key, value> mapping if one exists
  - void putAll(Map other) – put all <key, value> pairs from other into this map
  - Object get(Object key) – return the value associated with the given key, or null if key is not present
  - Object remove(Object key) – remove any mapping for the given key
  - boolean containsKey(Object key) – true if key appears in a <key, value> pair
  - boolean containsValue(Object value) – true if value appears in a <key, value>

Maps and Iteration

- Map provides methods to view contents of a map as a collection:
  - Set keySet( ) – return a Set whose elements are the keys of this map
  - Collection values( ) – return a Collection whose elements are the values contained in this map
  - [why is one a set and the other a collection?]
- To iterate through the keys or values or both, grab one of these collections, and then iterate through that

```
Map map = …;
Set keys = map.keySet( );
Iterator iter = keys.iterator( );
while (iter.hasNext( )) {
    Object key = iter.next( );
    Object value = map.get(key);
    …   // do something with key and value
}
```

interface SortedMap extends Map

- SortedMap can be used for maps where we want to store key/value pairs in order of their keys
  - Requires keys to be Comparable, using compareTo
- Sorting affects the order in which keys and values are iterated through
  - keySet( ) returns a SortedSet

Generic Collections – New in Java [1.]5

- Java 5/1.5 contains the first significant changes to the language in years
- Key change – generic collections: collections that can be specialized to hold particular kinds of objects & that guarantee type saftey
- Example

```
ArrayList<String> list = new ArrayList<String>();
list.add("Hi there");
list.add("Goodby");
String hello = list.get(0);          // no cast needed
list.add(new Integer(42));           // type error – won't compile
Rectangle r = list.get(1);           // type error – won't compile
```

Generics in Java [1.]5

- Java collection classes have been reworked to use generics extensively
  - JavaDocs now show types as, e.g., ArrayList<E>, Iterator<E>
  - Backward compatible with existing code, but you get warnings if you use naked collections (e.g., ArrayList) in a context where generic collections would provide more specific type info
- Available now for Linux, Windows
- Avaialble with Mac OS X 10.4 sometime this spring
- DrJava, Eclipse work with generics; other tools are adapting – some are already there, others soon
- Expect to see this in CSE14x within a year

Preview of Coming Attractions

1. Study ways to implement these interfaces
   - Array-based vs. link-list-based vs. hash-table-based vs. tree-based
2. Compare implementations
   - What does it mean to say one implementation is "faster" than another?
   - Basic complexity theory – O( ) notation
3. Use these and other data structures in our programming
