CSE 333

Lecture 8 - final C details, low-level I/O

Steve Gribble

Department of Computer Science & Engineering

University of Washington

Today's topics:

- a few final C details
  - header guards and other preprocessor tricks
  - extern, static and visibility of symbols
  - some topics for you to research on your own
- lower-level file access
  - open / read / write / close
    - instead of fopen / fread / fwrite / fclose

an #include problem

What happens when we compile foo.c?

```
typedef void *LinkedList;

// more definitions below
```
ll.h

```
#include "ll.h"

typedef void *HashTable;

// A hypothetical function
LinkedList HTKeyList(HashTable t);
```
ht.h

```
#include "ll.h"
#include "ht.h"

int main(int argc,
             char **argv) {
  // ... do stuff here ...
  return 0;
}
```
foo.c

an #include problem

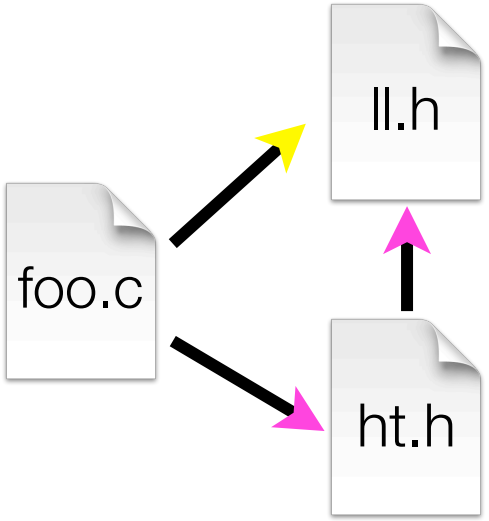
What happens when we compile foo.c?

```
bash$ gcc -Wall -g -o foo foo.c

In file included from ht.h:1,
                 from foo.c:2:
ll.h:1: error: redefinition of typedef 'LinkedList'
ll.h:1: note: previous declaration of 'LinkedList' was here
```

foo.c includes **ll.h** twice!

- 2nd time is indirectly via **ht.h**
- so, typedef shows up twice!
- *try using cpp to see this*



header guards

A commonly used C preprocessor trick to deal with this

- uses macro definition (#define)
- uses conditional compilation (#ifndef and #endif)

ll.h

```
#ifndef _LL_H_
#define _LL_H_ 1

typedef void *LinkedList;

// more definitions below

#endif  // _LL_H_
```

ht.h

```
#ifndef _HT_H_
#define _HT_H_

#include "ll.h"

typedef void *HashTable;

// A hypothetical function
LinkedList HTKeyList(HashTable t);

#endif  // _HT_H_
```

Other preprocessor tricks

A way to deal with “magic constants”

```
int globalbuffer[1000];

void circalc(float rad,
             float *circumf,
             float *area) {
  *circumf = rad * 2.0 * 3.1415;
  *area = rad * 3.1415 * 3.1415;
}
```

bad code
(littered with magic constants)

```
#define BUFSIZE 1000
#define PI 3.14159265359

int globalbuffer[BUFSIZE];

void circalc(float rad,
             float *circumf,
             float *area) {
  *circumf = rad * 2.0 * PI;
  *area = rad * 3.1415 * PI;
}
```

better code

Macros

You can pass arguments to macros

```
#define ODD(x) ((x) % 2 != 0)

void foo(void) {
   if ( ODD(5) )
     printf("5 is odd!\n");
}
```

```
void foo(void) {
   if ( ((5) % 2 != 0) )
     printf("5 is odd!\n");
}
```

Be careful of precedence issues; use parenthesis:

```
#define ODD(x) ((x) % 2 != 0)
#define BAD(x) x % 2 != 0

ODD(5 + 1);

BAD(5 + 1);
```

```
((5 + 1) % 2 != 0);

5 + 1 % 2 != 0;
```

Namespace problem

If I define a global variable named "counter" in foo.c, is it visible in bar.c?

- if you use **external linkage**: yes
  - the name "**counter**" refers to the same variable in both files
  - the variable is defined in one file, declared in the other(s)
  - when the program is linked, the symbol resolves to one location
- if you use **internal linkage**: no
  - the name "**counter**" refers to different variables in each file
  - the variable must be defined in each file
  - when the program is linked, the symbols resolve to two locations

External linkage

```
#include <stdio.h>

// A global variable, defined and
// initialized here in foo.c.
// It has external linkage by
// default.
int counter = 1;

int main(int argc, char **argv) {
  printf("%d\n", counter);
  bar();
  printf("%d\n", counter);
  return 0;
}
```

foo.c

```
#include <stdio.h>

// "counter" is defined and
// initialized in foo.c.
// Here, we declare it, and
// specify external linkage
// by using the extern
// specifier.
extern int counter;

void bar(void) {
  counter++;
  printf("(b): counter %d\n",
         counter);
}
```

bar.c

Internal linkage

```
#include <stdio.h>

// A global variable, defined and
// initialized here in foo.c.
// We force internal linkage by
// using the static specifier.
static int counter = 1;

int main(int argc, char **argv) {
  printf("%d\n", counter);
  bar();
  printf("%d\n", counter);
  return 0;
}
```

foo.c

```
#include <stdio.h>

// A global variable, defined and
// initialized here in bar.c.
// We force internal linkage by
// using the static specifier.
static int counter = 100;

void bar(void) {
  counter++;
  printf("(b): counter %d\n",
         counter);
}
```

bar.c

Some gotchas

Every global (variables and functions) is extern by default.

- unless you specify the static specifier, if some other module uses the same name, you'll end up with a collision!
  - best case: compiler error
  - worst case: stomp all over each other
- it's good practice to:
  - use static to defend your globals (hide your private stuff!)
  - place external (i.e., global) declarations in a module's header file

Extern, static functions

```
// By using the static specifier, we are indicating
// that foo() should have internal linkage.  Other
// .c files cannot see or invoke foo().
static int foo(int x) {
  return x*3 + 1;
}

// Bar is "extern" by default.  Thus, other .c files
// could declare our bar() and invoke it.
int bar(int x) {
  return 2*foo(x);
}
```

bar.c

```
#include <stdio.h>

extern int bar(int);

int main(int argc, char **argv) {
  printf("%d\n", bar(5));
  return 0;
}
```

main.c

Somebody should get fired

C has a second, different use for the word “static”

- to declare the extent of a local variable
- if you declare a static local variable, then:
  - the storage for that variable is allocated when the program loads, in either the program’s .data or .bss segment
  - the variable retains its value across multiple function invocations

(see static_extent.c for an example)

Additional C topics

Homework: teach yourself the following topics

- bit-level manipulation in C: **~ | & << >>**
- string library functions provided by the C standard library
  - #include <string.h>
    - strlen( ), strcp( ), strdup( ), strcat( ), strcmp( ), strchr( ), strstr( ), ...
    - learn why **strncat** is safer (in the security sense) than **strcat**, etc.
  - #include <stdlib.h> or #include <stdio.h>
    - atoi( ), atof( ), sprintf( ), sscanf( )
- **man** pages are your friend!

Additional C topics

Teach yourself:

- the syntax for function pointers, including passing as args
- how to declare, define, and use a function that accepts a variable-lengthed number of arguments (varargs)
- unions and what they are good for
- what argc and argv are for in main

```
#include <stdio.h>

int main(int argc, char **argv) {
  int i;

  for (i = 0; i < argc, i++) {
    printf("%d: %s\n", i, argv[i]);
  }
  return 0;
}
```

argv.c

```
bash$ gcc -o argv argv.c
bash$ ./argv
0: ./argv
bash$ ./argv foo bar
0: ./argv
1: foo
2: bar
bash$
```

Additional C topics

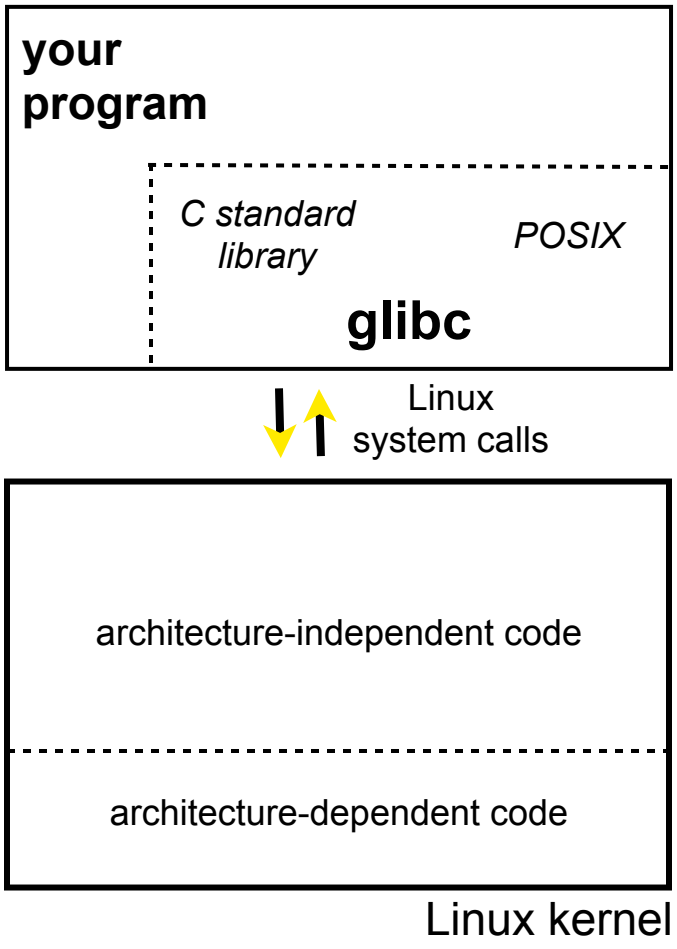
Teach yourself:

- the difference between pre-increment (++v) and post-increment (v++)
- the meaning of the “register” storage class
- harder: the meaning of the “volatile” storage class
  - pages 91, 92 of CARM

Lower-level file access

Remember this picture?

- your program can access many layers of APIs
  - C standard library
  - POSIX compatibility API
  - underlying OS system calls



So far...

You've used the C standard library to access files

- specifically, fopen, fread, fwrite, fclose, fseek
  - these provide a (FILE *) stream abstraction

These are convenient and portable...

- but, they are *buffered*
- and, they are implemented by using lower-level OS calls

Lower-level file access

Most UNIX-en support a common set of lower-level file access APIs

- open, read, write, close, fseek
  - similar in spirit to their fopen (etc.) counterparts
  - but, lower-level and unbuffered
  - and, less convenient
- you will have to use these for network I/O, so we might as well learn them now

open / close

To open a file...

- pass in the filename and access mode, similar to fopen
- get back a “file descriptor”
  - similar to a (FILE *) from fopen, but is just an int

```
#include <fcntl.h>

...

 int fd = open("foo.txt",
                O_RDONLY);
 if (fd == -1) {
   perror("open failed");
   exit(EXIT_FAILURE);
 }

...

 close(fd);
```

Reading from a file

ssize_t **read**(int fd, void *buf, size_t count);

- returns the # of bytes read
  - might be fewer bytes than you requested (!!!)
  - returns 0 if you're at end-of-file
  - return -1 on error
- warning: read has some very surprising error modes!

read( ) error modes

On error, the “errno” global variable is set

- you need to check it to see what kind of error happened

What errors might read( ) encounter?

- EBADF -- bad file descriptor
- EFAULT -- output buffer is not a valid address
- EINTR -- read was interrupted, please try again
  - argh!!!
- and many others

How to read( ) n bytes

```
#include <errno.h>
#include <unistd.h>

...

  char *buf = ...;
  int bytes_left = n;
  int result = 0;

  while (bytes_left > 0) {
     result = read(fd, buf + (n-bytes_left), bytes_left);
     if (result == -1) {
       if (errno != EINTR)) {
        // a real error happened, return an error result
       }
       // EINTR happened, do nothing and loop back around
       continue;
     }
     bytes_left -= result;
  }
```

Other low-level functions

Read the man pages to learn about:

- **write**( ) -- write data
- **fsync**( ) -- flush data to the underlying device
- **opendir**( ), **readdir**( ), **closedir**( ) -- get a directory listing
  - make sure you read the section 3 version, e.g.:
    - man 3 opendir
  - kind of painful to use

A useful cheat-sheet

From a CMU systems programming course:

http://www.cs.cmu.edu/~guna/15-123S11/Lectures/Lecture24.pdf

Exercise 1

Write a program that:

- prompts the user to input a string (use fgets( ))
  - assume the string is a sequence of whitespace-separated integers
  - e.g., “5555 1234 4 5543”
- converts the string into an array of integers
- converts an array of integers into an array of strings
  - where each element of the string array is the binary representation of the associated integer
- prints out the array of strings

Exercise 2

Modify the linked list code from last lecture / exercise 1

- add static declarations to any internal functions you impemented in linkedlist.h
- add a header guard to the header file
- write a Makefile
  - use Google to figure out how to add rules to the Makefile to produce a library (liblinkedlist.a) that contains the linked list code

See you on Wednesday!
