CSE 333 – Section 2: Structs and Debugging

In this class, it is very helpful to be comfortable with gdb and valgrind as debugging tools. gdb allows you to see the source code and has many useful commands for analyzing your program; valgrind catches many types of runtime memory errors.

Plenty of debugging resources can be found on the CSE351 GDB page and the CSE333 Debugging Page: https://courses.cs.washington.edu/courses/cse351/23sp/debugging/ and https://courses.cs.washington.edu/courses/cse333/23sp/debug/

Starting gdb

For gdb to work with your C/C++ program, you must compile it using the "-g" flag! To start up gdb, run the following command (the -tui flag is optional and enables a text UI).

\$ gdb -tui program file name>

Some essential gdb commands

If you want to know more, ask a TA or investigate the resources at the top of the page.

Setting Breakpoints and Continuing

break <where>Set a new breakpoint

• info breakpoints Prints information about the set breakpoints

• continue Continue normal execution

Controlling Program Execution

run <command_line_args> Run the program with provided command_line_args
 next Go to next instruction, but don't five into functions
 step Go to next instruction, and dive into functions
 finish Continue until current function returns

Examining the Current Program

• list Shows the current or given source context

close gdb

backtrace Shows the call stack
 up Moves up a stack frame
 down Moves down a stack frame

print <expression>
 Prints content of variable/memory location/register

Starting valgrind

quit

Note that valgrind only analyzes the code reached during a specific execution of your program. Run the following command:

\$ valgrind --leak-check=full ./program file name>

Section Code

Download full code:

wget https://courses.cs.washington.edu/courses/cse333/23au/sections/02/code/wordcount.c wget https://courses.cs.washington.edu/courses/cse333/23au/sections/02/code/Makefile

```
typedef struct word_st {
  char* word;
 int count; // The number of times the word appears
} WordCount;
// Increment the count by 1
void IncreaseCount(WordCount wc) {
 wc.count += 1;
}
// Capitalize the first letter in the word
void CapitalizeWord(WordCount* wc_ptr) {
 wc_ptr->word[0] &= ~0x20;
}
// Return a new WordCount with the letters of word in reverse
// order and a count of 0. Returns NULL on allocation failure.
WordCount ReverseWord(WordCount* wc_ptr) {
 WordCount* rev = (WordCount*) malloc(sizeof(WordCount));
  rev->word = NULL;
  strcpy(rev->word, wc_ptr->word);
 char ch;
  int L = 0, R = strlen(rev->word);
 while (L < R) {</pre>
    ch = rev->word[L];
    rev->word[L] = rev->word[R];
    rev->word[R] = ch;
    L++; R--;
  return *rev;
}
```

```
int main(int argc, char* argv[]) {
  char comp[] = "computer";
 WordCount comp_count = {comp, 5};
 WordCount* comp_ptr = &comp_count;
 // expecting "1. computer, 5"
 printf("1. %s, %d\n", comp_ptr->word, comp_ptr->count);
 IncreaseCount(*comp_ptr);
 // expecting "2. computer, 6"
  printf("2. %s, %d\n", comp_ptr->word, comp_ptr->count);
 CapitalizeWord(comp_ptr);
 // expecting "3. Computer, 6"
 printf("3. %s, %d\n", comp_ptr->word, comp_ptr->count);
  *comp_ptr = ReverseWord(comp_ptr);
 // expecting "4. retupmoC, 0"
 printf("4. %s, %d\n", comp_ptr->word, comp_ptr->count);
  return EXIT_SUCCESS;
}
```

Exercise 1

Draw a memory diagram for the execution of the code above up to the call to strcpy() in ReverseWord(). Make sure to distinguish between local variables on the Stack- and Heap-allocated memory.

Exercise 2

Feel free to make a few code changes based on your findings in Exercise 1. However, the rest of your time for this exercise should be spent in gdb and valgrind and NOT staring at the code. Find and fix all of the remaining logical and memory errors in the code and try to document/associate each fix with the tool features or output that led you there.

Please use the space below for documenting your errors fixed and tooling assistance.

Exercise 3

Fix any remaining style issues with the code in wordcount.c.
