

X86 Assembly, and C-to-assembly

- Move instructions, registers, and operands
- Complete addressing mode, address computation (`leal`)
- Arithmetic operations (including some x86-64 instructions)
- Condition codes
- Control, unconditional and conditional branches
- While loops

Three Kinds of Instructions

- **Perform arithmetic function on register or memory data**
 - $c = a + b;$

- **Transfer data between memory and register**
 - Load data from memory into register
 - $\%reg = Mem[address]$
 - Store register data into memory
 - $Mem[address] = \%reg$

- **Transfer control (control flow)**
 - Unconditional jumps to/from procedures
 - Conditional branches

Example

```
int t = x+y;
```

```
addl 8(%ebp), %eax
```

Similar to expression:

```
x += y
```

More precisely:

```
int eax;
int *ebp;
eax += ebp[2]
```

```
0x401046:    03 45 08
```

■ C Code

- Add two signed integers

■ Assembly

- Add 2 4-byte integers
 - “Long” words in GCC speak
 - Same instruction whether signed or unsigned
- Operands:
 - x**: Register **%eax**
 - y**: Memory **M[%ebp+8]**
 - t**: Register **%eax**

– Return function value in **%eax**

■ Object Code

- 3-byte instruction
- Stored at address **0x401046**

Moving Data: IA32

■ Moving Data

- `movx Source, Dest`
- `x` is one of {`b`, `w`, `l`}

- `movl Source, Dest`:
Move 4-byte “long word”
- `movw Source, Dest`:
Move 2-byte “word”
- `movb Source, Dest`:
Move 1-byte “byte”

■ Lots of these in typical code

`%eax`

`%ecx`

`%edx`

`%ebx`

`%esi`

`%edi`

`%esp`

`%ebp`

■ Operand Types

- **Immediate:** Constant integer data
 - Example: `$0x400`, `$-533`
 - Like C constant, but prefixed with ``$'`
 - Encoded with 1, 2, or 4 bytes
- **Register:** One of 8 integer registers
 - Example: `%eax`, `%edx`
 - But `%esp` and `%ebp` reserved for special use
 - Others have special uses for particular instructions
- **Memory:** 4 consecutive bytes of memory at address given by register
 - Simplest example: `(%eax)`
 - Various other “address modes”

<code>%eax</code>

movl Operand Combinations

	Source	Dest	Src, Dest	C Analog
movl	Imm	Reg	movl \$0x4, %eax	
		Mem	movl \$-147, (%eax)	
	Reg	Reg	movl %eax, %edx	
		Mem	movl %eax, (%edx)	
	Mem	Reg	movl (%eax), %edx	

Cannot do memory-memory transfer with a single instruction.

How do you copy from a memory location to another then?

movl Operand Combinations

	Source	Dest	Src, Dest	C Analog
movl	Imm	Reg	movl \$0x4, %eax	temp = 0x4;
		Mem	movl \$-147, (%eax)	*p = -147;
	Reg	Reg	movl %eax, %edx	temp2 = temp1;
		Mem	movl %eax, (%edx)	*p = temp;
	Mem	Reg	movl (%eax), %edx	temp = *p;

Simple Memory Addressing Modes

■ Normal (R) Mem[Reg[R]]

- Register R specifies memory address

```
movl (%ecx), %eax
```

■ Displacement D(R) Mem[Reg[R]+D]

- Register R specifies start of memory region
- Constant displacement D specifies offset

```
movl 8(%ebp), %edx
```

Using Simple Addressing Modes

```
void swap(int *xp, int *yp)
{
    int t0 = *xp;
    int t1 = *yp;
    *xp = t1;
    *yp = t0;
}
```

swap:

```
pushl %ebp
movl  %esp, %ebp
pushl %ebx
```

} Set
Up

```
movl 12(%ebp), %ecx
movl 8(%ebp), %edx
movl (%ecx), %eax
movl (%edx), %ebx
movl %eax, (%edx)
movl %ebx, (%ecx)
```

Complete Memory Addressing Modes

■ Most General Form

$D(Rb, Ri, S)$ $Mem[Reg[Rb]+S*Reg[Ri]+ D]$

- D: Constant “displacement” 1, 2, or 4 bytes
- Rb: Base register: Any of 8 integer registers
- Ri: Index register: Any, except for `%esp`
 - Unlikely you’d use `%ebp`, either
- S: Scale: 1, 2, 4, or 8 (*why these numbers?*)

■ Special Cases

(Rb, Ri) $Mem[Reg[Rb]+Reg[Ri]]$

$D(Rb, Ri)$ $Mem[Reg[Rb]+Reg[Ri]+D]$

(Rb, Ri, S) $Mem[Reg[Rb]+S*Reg[Ri]]$

Address Computation Examples

%edx	0xf000
%ecx	0x100

(Rb,Ri)

Mem[Reg[Rb]+Reg[Ri]]

D(Rb,Ri)

Mem[Reg[Rb]+Reg[Ri]+D]

(Rb,Ri,S)

Mem[Reg[Rb]+S*Reg[Ri]]

Expression	Address Computation	Address
0x8 (%edx)		
(%edx, %ecx)		
(%edx, %ecx, 4)		
0x80 (%edx, 2)		

Address Computation Examples

<code>%edx</code>	<code>0xf000</code>
<code>%ecx</code>	<code>0x100</code>

Expression	Address Computation	Address
<code>0x8 (%edx)</code>	<code>0xf000 + 0x8</code>	<code>0xf008</code>
<code>(%edx, %ecx)</code>	<code>0xf000 + 0x100</code>	<code>0xf100</code>
<code>(%edx, %ecx, 4)</code>	<code>0xf000 + 4*0x100</code>	<code>0xf400</code>
<code>0x80 (%edx, 2)</code>	<code>2*0xf000 + 0x80</code>	<code>0x1e080</code>

Address Computation Instruction

■ `leal Src, Dest`

- *Src* is address mode expression
- Set *Dest* to address denoted by expression

■ Uses

- Computing addresses without a memory reference
 - E.g., translation of `p = &x[i];`
- Computing arithmetic expressions of the form $x + k*i$
 - $k = 1, 2, 4, \text{ or } 8$

Some Arithmetic Operations

■ Two Operand Instructions:

subl *Src, Dest*

imull *Src, Dest*

sall *Src, Dest*

sarl *Src, Dest*

shrl *Src, Dest*

xorl *Src, Dest*

andl *Src, Dest*

orl *Src, Dest*

Computation

$Dest = Dest + Src$

$Dest = Dest - Src$

$Dest = Dest * Src$

$Dest = Dest \ll Src$

$Dest = Dest \gg Src$

$Dest = Dest \gg Src$

$Dest = Dest \wedge Src$

$Dest = Dest \& Src$

$Dest = Dest | Src$

xorl 12(%ebp),%eax
sarl $17,%eax
andl $8185,%eax
```

```
eax = x
eax = x^y      (t1)
eax = t1>>17  (t2)
eax = t2 & 8185
```

Another Example

```
int logical(int x, int y)
{
    int t1 = x^y;
    int t2 = t1 >> 17;
    int mask = (1<<13) - 7;
    int rval = t2 & mask;
    return rval;
}
```

$$2^{13} = 8192, 2^{13} - 7 = 8185$$

```
movl 8(%ebp), %eax
xorl 12(%ebp), %eax
sarl $17, %eax
andl $8185, %eax
```

logical:

```
pushl %ebp
movl %esp, %ebp
```

} Set
Up

```
movl 8(%ebp), %eax
xorl 12(%ebp), %eax
sarl $17, %eax
andl $8185, %eax
```

} Body

```
movl %ebp, %esp
popl %ebp
ret
```

} Finish

```
eax = x
eax = x^y      (t1)
eax = t1>>17  (t2)
eax = t2 & 8185
```

Control-Flow/Conditionals

■ Unconditional

```
while(true) {  
    do_something;  
}  
...
```

■ Conditional

```
int absdiff(int x, int y)  
{  
    int result;  
    if (x > y) {  
        result = x-y;  
    } else {  
        result = y-x;  
    }  
    return result;  
}
```

Conditionals and Control Flow

- **A test / conditional branch is sufficient to implement most control flow constructs offered in higher level languages**
 - if (condition) then {...} else {...}
 - while(condition) {...}
 - do {...} while (condition)
 - for (initialization; condition;) {...}
- **(Unconditional branches implemented some related control flow constructs**
 - break, continue)

Jumping

■ jX Instructions

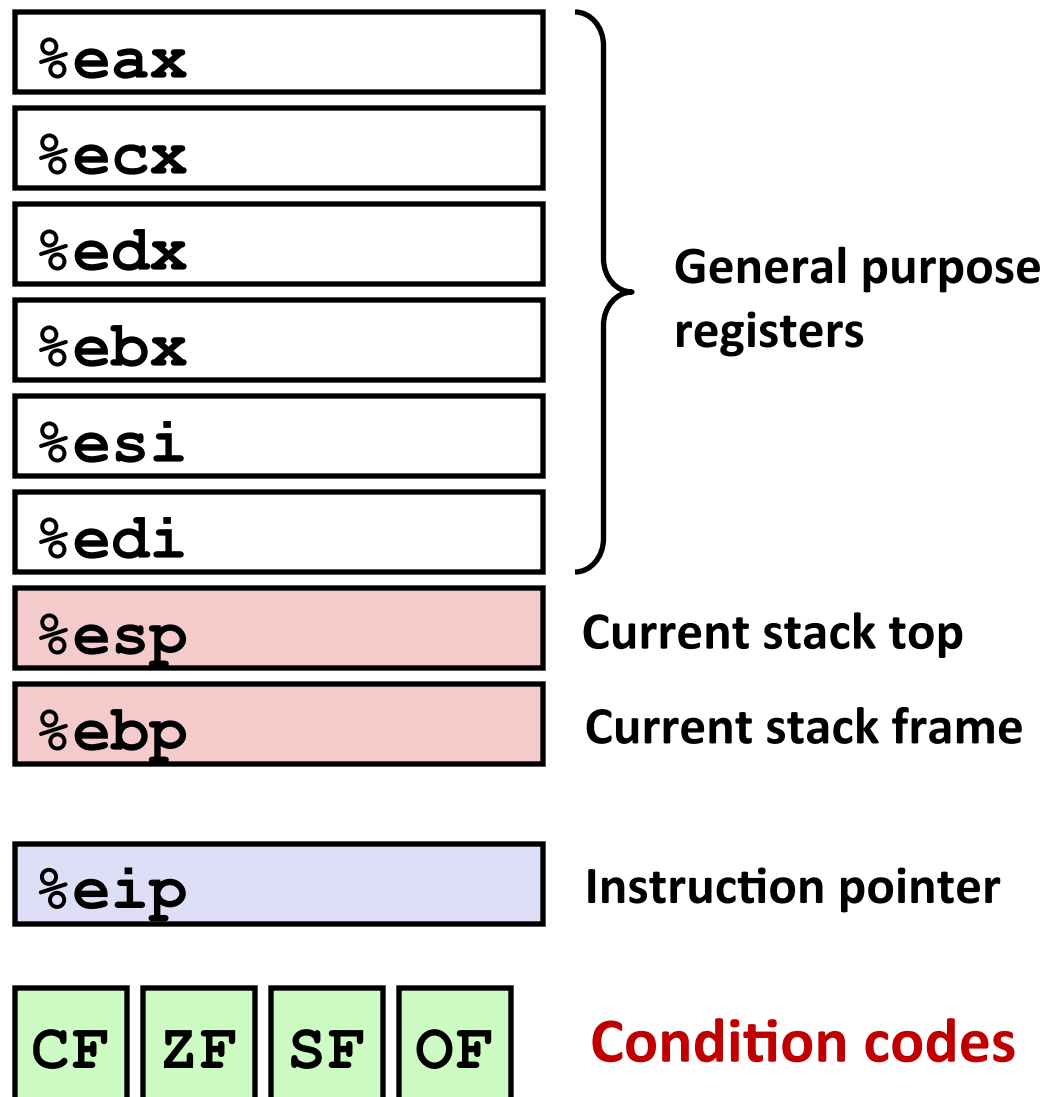

- Jump to different part of code depending on condition codes

jX	Condition	Description
jmp	1	Unconditional
je	ZF	Equal / Zero
jne	\sim ZF	Not Equal / Not Zero
js	SF	Negative
jns	\sim SF	Nonnegative
jg	\sim (SF \wedge OF) & \sim ZF	Greater (Signed)
jge	\sim (SF \wedge OF)	Greater or Equal (Signed)
jl	(SF \wedge OF)	Less (Signed)
jle	(SF \wedge OF) ZF	Less or Equal (Signed)
ja	\sim CF & \sim ZF	Above (unsigned)
jb	CF	Below (unsigned)

Processor State (IA32, Partial)

■ Information about currently executing program

- Temporary data (`%eax`, ...)
- Location of runtime stack (`%ebp`, `%esp`)
- Location of current code control point (`%eip`, ...)
- Status of recent tests (`CF`, `ZF`, `SF`, `OF`)

Condition Codes (Implicit Setting)

■ Single bit registers

CF Carry Flag (for unsigned)

SF Sign Flag (for signed)

ZF Zero Flag

OF Overflow Flag (for signed)

■ Implicitly set (think of it as side effect) by arithmetic operations

Example: `addl/addq Src, Dest` \leftrightarrow `t = a+b`

- **CF set** if carry out from most significant bit (unsigned overflow)

- **ZF set** if `t == 0`

- **SF set** if `t < 0` (as signed)

- **OF set** if two's complement (signed) overflow

`(a>0 && b>0 && t<0) || (a<0 && b<0 && t>=0)`

■ *Not* set by `leal` instruction (beware!)

■ Full documentation (IA32)

Condition Codes (Explicit Setting: Compare)

■ Explicit Setting by Compare Instruction

`cmpl/cmpq Src2,Src1`

`cmpl b, a` like computing `a-b` without setting destination

- **CF set** if carry out from most significant bit (used for unsigned comparisons)
- **ZF set** if `a == b`
- **SF set** if `(a-b) < 0` (as signed)
- **OF set** if two's complement (signed) overflow
`(a>0 && b<0 && (a-b)<0) || (a<0 && b>0 && (a-b)>0)`

Condition Codes (Explicit Setting: Test)

■ Explicit Setting by Test instruction

`testl / testq Src2,Src1`

`testl b,a` like computing `a&b` without setting destination

- Sets condition codes based on value of `Src1` & `Src2`
- Useful to have one of the operands be a mask
- ZF set when `a&b == 0`
- SF set when `a&b < 0`
- `testl %eax, %eax`
 - Sets SF and ZF, check if `eax` is +,0,-

Reading Condition Codes

■ SetX Instructions

- Set a single byte based on combinations of condition codes

SetX	Condition	Description
<code>sete</code>	ZF	Equal / Zero
<code>setne</code>	$\sim ZF$	Not Equal / Not Zero
<code>sets</code>	SF	Negative
<code>setns</code>	$\sim SF$	Nonnegative
<code>setg</code>	$\sim (SF \wedge OF) \ \& \ \sim ZF$	Greater (Signed)
<code>setge</code>	$\sim (SF \wedge OF)$	Greater or Equal (Signed)
<code>setl</code>	$(SF \wedge OF)$	Less (Signed)
<code>setle</code>	$(SF \wedge OF) \ \ ZF$	Less or Equal (Signed)
<code>seta</code>	$\sim CF \ \& \ \sim ZF$	Above (unsigned)
<code>setb</code>	CF	Below (unsigned)

Reading Condition Codes (Cont.)

■ SetX Instructions:

Set single byte based on combination of condition codes

■ One of 8 addressable byte registers

- Does not alter remaining 3 bytes
- Typically use `movzbl` to finish job

```
int gt (int x, int y)
{
    return x > y;
}
```

<code>%eax</code>	<code>%ah</code>	<code>%al</code>
<code>%ecx</code>	<code>%ch</code>	<code>%cl</code>
<code>%edx</code>	<code>%dh</code>	<code>%dl</code>
<code>%ebx</code>	<code>%bh</code>	<code>%bl</code>
<code>%esi</code>		
<code>%edi</code>		
<code>%esp</code>		
<code>%ebp</code>		

Body

```
movl 12(%ebp), %eax
cmpl %eax, 8(%ebp)
setg %al
movzbl %al, %eax
```

What does each of these instructions do?

General Conditional Expression Translation

C Code

```
val = Test ? Then-Expr : Else-Expr;
```

```
val = x > y ? x - y : y - x;
```

Goto Version

```
nt = !Test;  
if (nt) goto Else;  
val = Then-Expr;  
Done:  
. . .  
Else:  
val = Else-Expr;  
goto Done;
```

- *Test* is expression returning integer
= 0 interpreted as false
≠ 0 interpreted as true
- Create separate code regions for then & else expressions
- Execute appropriate one
- How would you make this efficient?

Conditionals: x86-64

```

int absdiff(
    int x, int y)
{
    int result;
    if (x > y) {
        result = x-y;
    } else {
        result = y-x;
    }
    return result;
}

```

```

absdiff: # x in %edi, y in %esi
    movl   %edi, %eax   # eax = x
    movl   %esi, %edx   # edx = y
    subl   %esi, %eax   # eax = x-y
    subl   %edi, %edx   # edx = y-x
    cmpl   %esi, %edi   # x:y
    cmovle %edx, %eax   # eax=edx if <=
    ret

```

■ Conditional move instruction

- `cmovC src, dest`
- Move value from src to dest if condition *C* holds
- More efficient than conditional branching (simple control flow)
- But overhead: both branches are evaluated

PC Relative Addressing

0x100	cmp	r2, r3	0x1000
0x102	je	0x70	0x1002
0x104	...		0x1004
...
0x172	add	r3, r4	0x1072

- PC relative branches are relocatable
- Absolute branches are not

Compiling Loops

C/Java code

```
while ( sum != 0 ) {  
    <loop body>  
}
```

Machine code

```
loopTop:    cmp    r3, $0  
            be    loopDone  
            <loop body code>  
            jmp  loopTop  
loopDone:
```

- **How to compile other loops should be clear to you**
 - The only slightly tricky part is to be sure where the conditional branch occurs: top or bottom of the loop
- **Q: How is `for (i=0; i<100; i++)` implemented?**
- **Q: How are `break` and `continue` implemented?**

Machine Programming II: Instructions (cont'd)

- Move instructions, registers, and operands
- Complete addressing mode, address computation (`leal`)
- Arithmetic operations (including some x86-64 instructions)
- Condition codes
- Control, unconditional and conditional branches
- **While loops**
- **For loops**
- **Switch statements**

“Do-While” Loop Example

C Code

```
int fact_do(int x)
{
    int result = 1;
    do {
        result *= x;
        x = x-1;
    } while (x > 1);
    return result;
}
```

Goto Version

```
int fact_goto(int x)
{
    int result = 1;
loop:
    result *= x;
    x = x-1;
    if (x > 1) goto loop;
    return result;
}
```

- Use backward branch to continue looping
- Only take branch when “while” condition holds

“Do-While” Loop Compilation

Goto Version

```
int
fact_goto(int x)
{
    int result = 1;

loop:
    result *= x;
    x = x-1;
    if (x > 1)
        goto loop;

    return result;
}
```

Assembly

```
fact_goto:
    pushl %ebp
    movl %esp,%ebp
    movl $1,%eax
    movl 8(%ebp),%edx

.L11:
    imull %edx,%eax
    decl %edx
    cmpl $1,%edx
    jg .L11

    movl %ebp,%esp
    popl %ebp
    ret
```

Registers:

%edx	x
%eax	result

Translation?

“Do-While” Loop Compilation

Goto Version

```
int
fact_goto(int x)
{
    int result = 1;

loop:
    result *= x;
    x = x-1;
    if (x > 1)
        goto loop;

    return result;
}
```

Assembly

```
fact_goto:
    pushl %ebp                # Setup
    movl %esp,%ebp          # Setup
    movl $1,%eax            # eax = 1
    movl 8(%ebp),%edx        # edx = x

.L11:
    imull %edx,%eax         # result *= x
    decl %edx                # x--
    cmpl $1,%edx            # Compare x : 1
    jg .L11                  # if > goto loop

    movl %ebp,%esp          # Finish
    popl %ebp                # Finish
    ret                       # Finish
```

Registers:

%edx	x
%eax	result

General “Do-While” Translation

C Code

```
do  
  Body  
while (Test);
```

Goto Version

```
loop:  
  Body  
  if (Test)  
    goto loop
```

- *Body*: {
 *Statement*₁;
 *Statement*₂;
 ...
 *Statement*_{*n*};
}

- *Test* returns integer
 = 0 interpreted as false
 ≠0 interpreted as true

“While” Loop Example

C Code

```
int fact_while(int x)
{
    int result = 1;
    while (x > 1) {

        result *= x;
        x = x-1;
    };

    return result;
}
```

Goto Version #1

```
int fact_while_goto(int x)
{
    int result = 1;
loop:
    if (!(x > 1))
        goto done;
    result *= x;
    x = x-1;
    goto loop;
done:
    return result;
}
```

- Is this code equivalent to the do-while version?
- Must jump out of loop if test fails

Alternative “While” Loop Translation

C Code

```
int fact_while(int x)
{
    int result = 1;
    while (x > 1) {
        result *= x;
        x = x-1;
    };
    return result;
}
```

Goto Version #2

```
int fact_while_goto2(int x)
{
    int result = 1;
    if (!(x > 1))
        goto done;
loop:
    result *= x;
    x = x-1;
    if (x > 1)
        goto loop;
done:
    return result;
}
```

- Historically used by GCC
- Uses same inner loop as do-while version
- Guards loop entry with extra test

General “While” Translation

While version

```
while (Test)  
  Body
```

Do-While Version

```
if (!Test)  
  goto done;  
do  
  Body  
  while (Test) ;  
done:
```

Goto Version

```
if (!Test)  
  goto done;  
loop:  
  Body  
  if (Test)  
    goto loop;  
done:
```

New Style “While” Loop Translation

C Code

```
int fact_while(int x)
{
    int result = 1;
    while (x > 1) {
        result *= x;
        x = x-1;
    };
    return result;
}
```

Goto Version

```
int fact_while_goto3(int x)
{
    int result = 1;
    goto middle;
loop:
    result *= x;
    x = x-1;
middle:
    if (x > 1)
        goto loop;
    return result;
}
```

- Recent technique for GCC
 - Both IA32 & x86-64
- First iteration jumps over body computation within loop

Jump-to-Middle While Translation

C Code

```
while (Test)  
    Body
```

Goto Version

```
goto middle;  
loop:  
    Body  
middle:  
    if (Test)  
        goto loop;
```

- Avoids duplicating test code
- Unconditional goto incurs no performance penalty
- for loops compiled in similar fashion

Goto (Previous) Version

```
if (!Test)  
    goto done;  
loop:  
    Body  
    if (Test)  
        goto loop;  
done:
```

Jump-to-Middle Example

```
int fact_while(int x)
{
    int result = 1;
    while (x > 1) {
        result *= x;
        x--;
    };
    return result;
}
```

```
# x in %edx, result in %eax
    jmp    .L34          # goto Middle
.L35:                # Loop:
    imull %edx, %eax    # result *= x
    decl  %edx          # x--
.L34:                # Middle:
    cmpl  $1, %edx     # x:1
    jg    .L35          # if >, goto Loop
```

Quick Review

- Complete memory addressing mode
 - `(%eax), 17(%eax), 2(%ebx, %ecx, 8), ...`

- Arithmetic operations that do set condition codes
 - `subl %eax, %ecx` # `ecx = ecx + eax`
 - `sall $4, %edx` # `edx = edx << 4`
 - `addl 16(%ebp), %ecx` # `ecx = ecx + Mem[16+ebp]`
 - `imull %ecx, %eax` # `eax = eax * ecx`

- Arithmetic operations that do NOT set condition codes
 - `leal 4(%edx, %eax), %eax` # `eax = 4 + edx + eax`

Quick Review

■ x86-64 vs. IA32

- Integer registers: **16 x 64-bit** vs. **8 x 32-bit**
- **movq, addq, ...** vs. **movl, addl, ...**
- Better support for passing function arguments in registers

%rax	%eax	%r8	%r8d
%rbx	%ebx	%r9	%r9d
%rcx	%ecx	%r10	%r10d
%rdx	%edx	%r11	%r11d
%rsi	%esi	%r12	%r12d
%rdi	%edi	%r13	%r13d
%rsp	%esp	%r14	%r14d
%rbp	%ebp	%r15	%r15d

■ Control

- Condition code registers
- Set as side effect or by **cmp, test**
- Used:
 - Read out by setx instructions (**setg, setle, ...**)
 - Or by conditional jumps (**jle .L4, je .L10, ...**)

■ Algorithm

- Exploit bit representation: $p = p_0 + 2p_1 + 2^2p_2 + \dots + 2^{n-1}p_{n-1}$
- Gives: $x^p = z_0 \cdot z_1^2 \cdot (z_2^2)^2 \cdot \dots \cdot \underbrace{(\dots((z_{n-1}^2)^2)\dots)^2}_{n-1 \text{ times}}$
 - $z_i = 1$ when $p_i = 0$
 - $z_i = x$ when $p_i = 1$
- Complexity $O(\log p)$

Example

$$\begin{aligned}
 3^{10} &= 3^2 * 3^8 \\
 &= 3^2 * ((3^2)^2)^2
 \end{aligned}$$

ipwr Computation

```

/* Compute x raised to nonnegative power p */
int ipwr_for(int x, unsigned p)
{
    int result;
    for (result = 1; p != 0; p = p>>1) {
        if (p & 0x1)
            result *= x;
        x = x*x;
    }
    return result;
}

```

Assembly Setup Explanation

■ Table Structure

- Each target requires 4 bytes
- Base address at `.L62`

■ Jumping

Direct: `jmp .L61`

- Jump target is denoted by label `.L61`

Indirect: `jmp *.L62(, %edx, 4)`

- Start of jump table: `.L62`
- Must scale by factor of 4 (labels have 32-bit = 4 Bytes on IA32)
- Fetch target from effective Address `.L62 + edx*4`
 - Only for $0 \leq x \leq 6$

Jump table

```
.section .rodata
    .align 4
.L62:
    .long    .L61    # x = 0
    .long    .L56    # x = 1
    .long    .L57    # x = 2
    .long    .L58    # x = 3
    .long    .L61    # x = 4
    .long    .L60    # x = 5
    .long    .L60    # x = 6
```

Jump Table

    .align 4
.L62:
    .long    .L61    # x = 0
    .long    .L56    # x = 1
    .long    .L57    # x = 2
    .long    .L58    # x = 3
    .long    .L61    # x = 4
    .long    .L60    # x = 5

switch(x) {
case 1:      // .L56
    w = y*z;
    break;
case 2:      // .L57
    w = y/z;
    /* Fall Through */
case 3:      // .L58

case 6:      // .L60
    w -= z;
    break;
default:    // .L61
    w = 2;
}
  
```

The diagram illustrates the mapping between assembly code and C code. Red arrows connect the labels in the assembly code to their corresponding cases in the C switch statement:

- `.L61` (assembly) maps to `case 1` (C)
- `.L56` (assembly) maps to `case 2` (C)
- `.L57` (assembly) maps to `case 3` (C)
- `.L58` (assembly) maps to `case 5` (C)
- `.L61` (assembly) maps to `default` (C)
- `.L60` (assembly) maps to `case 6` (C)

Code Blocks (Partial)

```

case 2:      // .L57
    w = y/z;
    /* Fall Through */
case 3:      // .L58
    w += z;
    break;
    . . .
default:    // .L61
    w = 2;
}

```

```

Matching Disassembled Targets

Summarizing

■ C Control

- if-then-else
- do-while
- while, for
- switch

■ Assembler Control

- Conditional jump
- Conditional move
- Indirect jump
- Compiler
- Must generate assembly code to implement more complex control

■ Standard Techniques

- Loops converted to do-while form
- Large switch statements use jump tables
- Sparse switch statements may use decision trees (see text)

■ Conditions in CISC

- CISC machines generally have condition code registers
