

## Graphs: Shortest Paths (Chapter 9)

CSE 373  
Data Structures and Algorithms

11/07/2012

1

### Today's Outline

- **Admin:**
  - Homework #4 - due Thurs, Nov 8<sup>th</sup> at 11pm
  - Midterm 2, Fri Nov 16
- **Graphs**
  - Graph Traversals
  - Shortest Paths

11/07/2012

2

### Single source shortest paths

- Done: BFS to find the minimum path length from  $v$  to  $u$  in  $O(|E| + |V|)$
- Actually, can find the minimum path length from  $v$  to *every node*
  - Still  $O(|E| + |V|)$
  - No faster way for a “distinguished” destination in the worst-case
- Now: Weighted graphs
  - Given a weighted graph and node  $v$ ,
  - find the minimum-cost path from  $v$  to every node
- As before, asymptotically no harder than for one destination
- Unlike before, BFS will not work

11/07/2012

3

### Applications

- Network routing
- Driving directions
- Cheap flight tickets
- Critical paths in project management (see textbook)
- ...

---

---

---

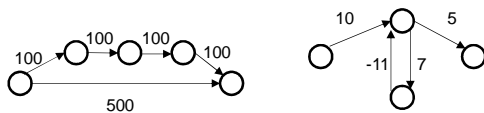

---

---

---

---

### Not as easy

Why BFS won't work: Shortest path may not have the fewest edges

- Annoying when this happens with costs of flights

We will assume there are no negative weights

- Problem is ill-defined if there are negative-cost *cycles*
- Next algorithm we will learn is wrong if *edges* can be negative

11/07/2012

5

---

---

---

---

---

---

---

### Edsger Wybe Dijkstra (1930-2002)

- Legendary figure in computer science; was a professor at University of Texas.
- Invented concepts of structured programming, synchronization, and "semaphores" for controlling computer processes.
- Supported teaching programming without computers (pencil and paper)
- 1972 Turing Award
- "computer science is no more about computers than astronomy is about telescopes"

11/07/2012

6

---

---

---

---

---

---

---

### Dijkstra's Algorithm

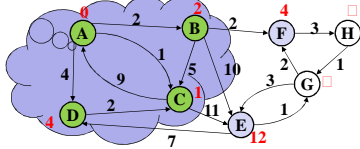

The idea: reminiscent of BFS, but adapted to handle weights

- A priority queue will prove useful for efficiency (later)
- Will grow the set of nodes whose shortest distance has been computed
- Nodes not in the set will have a "best distance so far"

11/07/2012

7

### Dijkstra's Algorithm: Idea

- Initially, start node (A in this case) has "cost" 0 and all other nodes have "cost"  $\infty$
- At each step:
  - Pick closest unknown vertex  $v$
  - Add it to the "cloud" of known vertices
  - Update "costs" for nodes with edges from  $v$
- That's it! (Have to prove it produces correct answers)

11/07/2012

8

### The Algorithm

1. For each node  $v$ , set  $v.cost = \infty$  and  $v.known = false$
2. Set  $source.cost = 0$
3. While there are unknown nodes in the graph
  - a) Select the unknown node  $v$  with lowest cost
  - b) Mark  $v$  as known
  - c) For each edge  $(v, u)$  with weight  $w$ ,
 

```

c1 = v.cost + w // cost of best path through v to u
c2 = u.cost // cost of best path to u previously known
if (c1 < c2) { // if the path through v is better
    u.cost = c1
    u.path = v // for computing actual paths
}
          
```

11/07/2012

9

*Important features*

- Once a vertex is marked known, the cost of the shortest path to that node is known
  - As is the path itself
- While a vertex is still not known, another shorter path to it might still be found

11/07/2012

10

---

---

---

---

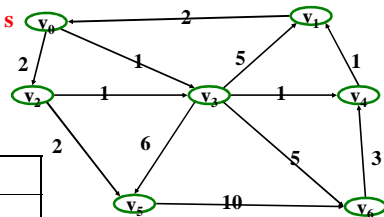

---

---

---

---

Find the shortest path to each vertex from  $v_0$

Order declared Known:

V	Known	Dist from s	Path
v0			
v1			
v2			
v3			
v4			
v5			
v6			

11

---

---

---

---

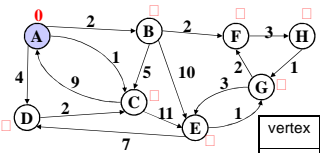

---

---

---

---

*Example #1*

vertex	known?	cost	path
A			
B			
C			
D			
E			
F			
G			
H

Example #1

vertex	known?	cost	path
A	Y	0	
B	Y	2	A
C	Y	1	A
D	Y	4	A
E	Y	11	G
F	Y	4	B
G	Y	8	H
H	Y	7	F

11/07/2012

21

---

---

---

---

---

---

---

---

### Important features

- Once a vertex is marked 'known', the cost of the shortest path to that node is known
  - As is the path itself
- While a vertex is still not known, another shorter path to it might still be found

11/07/2012

22

---

---

---

---

---

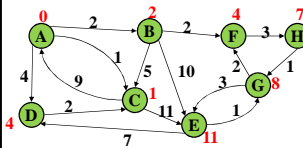

---

---

---

### Interpreting the results

- Now that we're done, how do we get the path from, say, A to E?

vertex	known?	cost	path
A	Y	0	
B	Y	2	A
C	Y	1	A
D	Y	4	A
E	Y	11	G
F	Y	4	B
G	Y	8	H
H	Y	7	F

11/07/2012

23

---

---

---

---

---

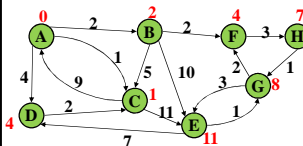

---

---

---

### Stopping Short

- How would this have worked differently if we were only interested in the path from A to G?
  - A to E?

vertex	known?	cost	path
A	Y	0	
B	Y	2	A
C	Y	1	A
D	Y	4	A
E	Y	11	G
F	Y	4	B
G	Y	8	H
H	Y	7	F

11/07/2012

24

---

---

---

---

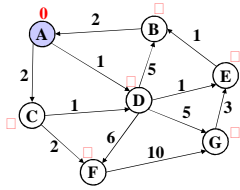

---

---

---

---

Example #2

vertex	known?	cost	path
A		0	
B		??	
C		??	
D		??	
E		??	
F		??	
G		??	

11/07/2012

25

---

---

---

---

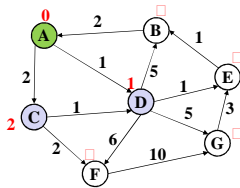

---

---

---

---

Example #2

vertex	known?	cost	path
A	Y	0	
B		??	
C		$\leq 2$	A
D		$\leq 1$	A
E		??	
F		??	
G		??	

11/07/2012

26

---

---

---

---

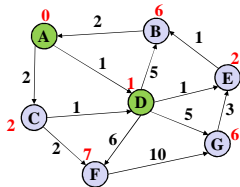

---

---

---

---

Example #2

vertex	known?	cost	path
A	Y	0	
B		$\leq 6$	D
C		$\leq 2$	A
D	Y	1	A
E		$\leq 2$	D
F		$\leq 7$	D
G		$\leq 6$	D

11/07/2012

27

---

---

---

---

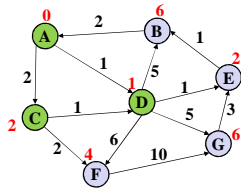

---

---

---

---

Example #2

vertex	known?	cost	path
A	Y	0	
B		$\leq 6$	D
C	Y	2	A
D	Y	1	A
E		$\leq 2$	D
F		$\leq 4$	C
G		$\leq 6$	D

11/07/2012

28

---

---

---

---

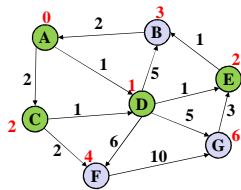

---

---

---

---

Example #2

vertex	known?	cost	path
A	Y	0	
B		$\leq 3$	E
C	Y	2	A
D	Y	1	A
E	Y	2	D
F		$\leq 4$	C
G		$\leq 6$	D

11/07/2012

29

---

---

---

---

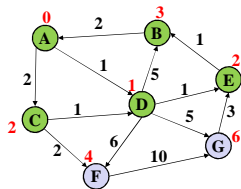

---

---

---

---

Example #2

vertex	known?	cost	path
A	Y	0	
B	Y	3	E
C	Y	2	A
D	Y	1	A
E	Y	2	D
F		$\leq 4$	C
G		$\leq 6$	D

11/07/2012

30

---

---

---

---

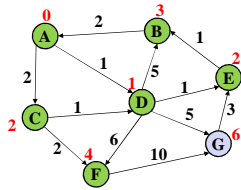

---

---

---

---

Example #2

vertex	known?	cost	path
A	Y	0	
B	Y	3	E
C	Y	2	A
D	Y	1	A
E	Y	2	D
F	Y	4	C
G		$\leq 6$	D

11/07/2012

31

---

---

---

---

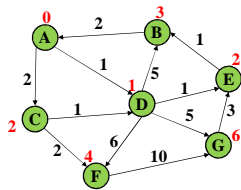

---

---

---

---

Example #2

vertex	known?	cost	path
A	Y	0	
B	Y	3	E
C	Y	2	A
D	Y	1	A
E	Y	2	D
F	Y	4	C
G	Y	6	D

11/07/2012

32

---

---

---

---

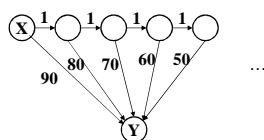

---

---

---

---

Example #3

How will the best-cost-so-far for Y proceed?

Is this expensive?

11/07/2012

33

---

---

---

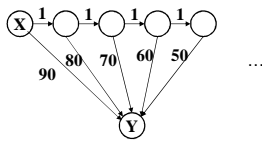

---

---

---

---

---

**Example #3**

How will the best-cost-so-far for Y proceed? 90, 81, 72, 63, 54, ...

Is this expensive? No, each edge is processed only once

11/07/2012

34

**A Greedy Algorithm**

- Dijkstra's algorithm
  - For single-source shortest paths in a weighted graph (directed or undirected) with no negative-weight edges
  - An example of a *greedy algorithm*:
    - at each step, irrevocably does what seems best at that step (once a vertex is in the known set, does not go back and readjust its decision)
    - Locally optimal – does not always mean globally optimal

11/07/2012

35

**Where are we?**

- Have described Dijkstra's algorithm
  - For single-source shortest paths in a weighted graph (directed or undirected) with no negative-weight edges
- What should we do after learning an algorithm?
  - Prove it is correct
    - Not obvious!
    - We will sketch the key ideas
  - Analyze its efficiency
    - Will do better by using a data structure we learned earlier!

11/07/2012

36

### Correctness: Intuition

Rough intuition:

All the "known" vertices have the correct shortest path

- True initially: shortest path to start node has cost 0
- If it stays true every time we mark a node "known", then by induction this holds and eventually everything is "known"

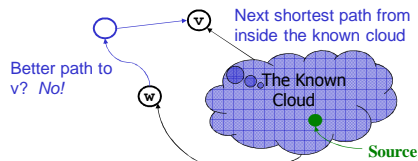

Key fact we need: When we mark a vertex "known" we won't discover a shorter path later!

- This holds only because Dijkstra's algorithm picks the node with the next shortest path-so-far
- The proof is by contradiction...

11/07/2012

37

### Correctness: The Cloud (Rough Idea)

Suppose  $v$  is the next node to be marked known ("added to the cloud")

- The **best-known** path to  $v$  must have only nodes "in the cloud"
  - Since we've selected it, and we only know about paths through the cloud to a node right outside the cloud
- Assume the **actual shortest** path to  $v$  is different
  - It won't use only cloud nodes, (or we would know about it), so it must use non-cloud nodes
  - Let  $w$  be the *first* non-cloud node on this path.
  - The part of the path up to  $w$  is *already known* and must be shorter than the best-known path to  $v$ . So  $v$  would not have been picked. Contradiction.

11/07/2012

38

### Efficiency, first approach

Use pseudocode to determine asymptotic run-time

- Notice each edge is processed only once

```

dijkstra(Graph G, Node start) {
  for each node: x.cost=infinity, x.known=false
  start.cost = 0
  while(not all nodes are known) {
    b = find unknown node with smallest cost
    b.known = true
    for each edge (b,a) in G
      if(!a.known)
        if(b.cost + weight((b,a)) < a.cost){
          a.cost = b.cost + weight((b,a))
          a.path = b
        }
  }
}
  
```

11/07/2012

39

### Efficiency, first approach

Use pseudocode to determine asymptotic run-time

- Notice each edge is processed only once

```
dijkstra(Graph G, Node start) {
  for each node: x.cost=infinity, x.known=false } O(|V|)
  start.cost = 0
  while(not all nodes are known) {
    b = find unknown node with smallest cost } O(|V|^2)
    b.known = true
    for each edge (b,a) in G
      if(!a.known)
        if(b.cost + weight((b,a)) < a.cost){ } O(|E|)
          a.cost = b.cost + weight((b,a))
          a.path = b
        }
  }
```

11/07/2012

40

### Improving asymptotic running time

- So far:  $O(|V|^2)$
- We had a similar “problem” with topological sort being  $O(|V|^2)$  due to each iteration looking for the node to process next
  - We solved it with a queue of zero-degree nodes
  - But here we need the lowest-cost node and costs can change as we process edges
- Solution?

11/07/2012

41

### Improving (?) asymptotic running time

- So far:  $O(|V|^2)$
- We had a similar “problem” with topological sort being  $O(|V|^2)$  due to each iteration looking for the node to process next
  - We solved it with a queue of zero-degree nodes
  - But here we need the lowest-cost node and costs can change as we process edges
- Solution?
  - A priority queue holding all unknown nodes, sorted by cost
  - But must support **decreaseKey** operation
    - Must maintain a reference from each node to its position in the priority queue
    - Conceptually simple, but can be a pain to code up

11/07/2012

42

### Efficiency, second approach

Use pseudocode to determine asymptotic run-time

```
dijkstra(Graph G, Node start) {
  for each node: x.cost=infinity, x.known=false }
  start.cost = 0
  build-heap with all nodes
  while(heap is not empty) {
    b = deleteMin()
    b.known = true
    for each edge (b,a) in G
      if(!a.known)
        if(b.cost + weight((b,a)) < a.cost){
          decreaseKey(a,"new cost - old cost")
          a.path = b
        }
      }
  }
```

11/07/2012

43

---

---

---

---

---

---

---

---

### Efficiency, second approach

Use pseudocode to determine asymptotic run-time

```
dijkstra(Graph G, Node start) {
  for each node: x.cost=infinity, x.known=false } O(|V|)
  start.cost = 0
  build-heap with all nodes
  while(heap is not empty) {
    b = deleteMin()
    b.known = true
    for each edge (b,a) in G
      if(!a.known)
        if(b.cost + weight((b,a)) < a.cost){
          decreaseKey(a,"new cost - old cost") O(|E|log|V|)
          a.path = b
        }
      }
  } O(|V|log|V|+|E|log|V|)
```

11/07/2012

44

---

---

---

---

---

---

---

---

### Dense vs. sparse again

- First approach:  $O(|V|^2)$
- Second approach:  $O(|V|\log|V|+|E|\log|V|)$
- So which is better?
  - Sparse:  $O(|V|\log|V|+|E|\log|V|)$  (if  $|E| > |V|$ , then  $O(|E|\log|V|)$ )
  - Dense:  $O(|V|^2)$
- But, remember these are worst-case and asymptotic
  - Priority queue might have slightly worse constant factors
  - On the other hand, for "normal graphs", we might call `decreaseKey` rarely (or not percolate far), making  $|E|\log|V|$  more like  $|E|$

11/07/2012
