

Variations on the basic problem

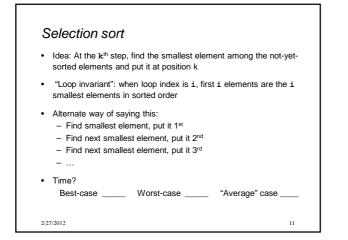

- Maybe elements are in a linked list (could convert to array and back in linear time, but some algorithms needn't do so)
- 2. Maybe in the case of ties we should preserve the original ordering - Sorts that do this naturally are called stable sorts
 - One way to sort twice, Ex: Sort movies by year, then for ties,
- alphabetically 3. Maybe we must not use more than *O*(1) "auxiliary space"
 - Sorts meeting this requirement are called 'in-place' sorts
 - Not allowed to allocate extra array (at least not with size O(n)), but can allocate O(1) # of variables
 - All work done by swapping around in the array
- 4. Maybe we can do more with elements than just compare
 - Comparison sorts assume we work using a binary 'compare' operator
 In special cases we can sometimes get faster algorithms
- Maybe we have too much data to fit in memory
 - Use an "external sorting" algorithm

Insertion Sort vs. Selection Sort

- They are different algorithms
- They solve the same problem
- They have the same worst-case and average-case asymptotic complexity
 - Insertion sort has better best-case complexity; preferable when input is "mostly sorted"
- Other algorithms are more efficient for larger arrays that are not already almost sorted
 - Small arrays may do well with Insertion sort

Aside: We won't cover Bubble Sort

- It doesn't have good asymptotic complexity: O(n²)
- · It's not particularly efficient with respect to common factors
- Basically, almost everything it is good at, some other algorithm
 is at least as good at
- Some people seem to teach it just because someone taught it to them
- For fun see: "Bubble Sort: An Archaeological Algorithmic Analysis", Owen Astrachan, SIGCSE 2003
