Fall 2017

Lecture 11 – gdb and Debugging

Administrivia

- HW4 out now, due next Thursday, Oct. 26, 11 pm:
 - C code and libraries.
 - Some tools: gdb (debugger) and clint.py (style checker). gdb demo today.
 - Due next Thursday, 11 pm
- Midterm the following Wednesday, Nov. 1, in class
 - Everything up to hw4/basic C
 - Closed book – will provide reference summary info on test as needed
 - Old exams on web now for studying
 - Review Q&A Tuesday, Oct. 31, 4:30, location TBA

Agenda

- Debuggers, particularly gdb
- Why?
 - To learn general features of breakpoint-debugging
 - To learn specifics of gdb
 - To learn general debugging “survival skills”
 - Skill #1: don’t panic!
 - Skill #2: be systematic – have a plan

How to avoid debugging

- Don't put bugs in the program!!
- Think before typing – design before coding
- Write down design (comments) as you go
 - Functions: declaration+comments should be complete spec
 - Significant data: declaration + comments should be complete spec
 - If someone has to read the code to figure out how to use something or understand data structures, comments are bad
 - Review/check comments and compare to code as you work
 - Will catch errors before you run the program
- Turn on compiler warnings (-Wall); use assert; get the computer to find problems for you.
- But things can still go wrong...

An execution monitor?

- What would you like to “see inside” and “do to” a running program?
- Why might all that be helpful?
- What are reasonable ways to debug a program?
- A “debugger” is a tool that lets you stop running programs, inspect (sometimes set) values, run a statement or two at a time, etc.
 - A “MRI” for observing executing code

Issues

- Source information for compiled code. (Get compiler help)
- Stopping your program too late to find the problem. (Art)
- Trying to “debug” the wrong algorithm
- Trying to “run the debugger” instead of understanding the program
- It’s an important tool
- Debugging C vs. Java
 - Eliminating crashes does not make your C program correct
 - Debugging Java is “easier” because (some) crashes and memory errors do not exist
 - But programming Java is “easier” for the same reason!

`gdb`

- `gdb` (Gnu debugger) is part of the standard Linux toolchain.
- `gdb` supports several languages, including C compiled by `gcc`.
- Modern IDEs have fancy GUI interfaces, which help, but concepts are the same.
- Compile with debugging information: `gcc -g`
 - Otherwise, `gdb` can tell you little more than the stack of function calls.
- Running `gdb`: `gdb executable`
 - Source files should be in same directory (or use the `-d` flag).
- At prompt: `run args`
- Note: You can also inspect core files, which is why they got saved on older systems after every crash
 - (Mostly useful for analyzing crashed programs after-the-fact, not for systematic debugging. The original use of `db`.)

Basic functions

- backtrace
- frame, up, down
- print expression, info args, info locals

Often enough for “crash debugging”

Also often enough for learning how “the compiler does things” (e.g., stack direction, malloc policy, ...)

Breakpoints

- break function (or line-number or ...)
- conditional breakpoints (break XXX if expr)
 1. to skip a bunch of iterations
 2. to do assertion checking
- going forward: continue, next, step, finish
 - Some debuggers let you “go backwards” (typically an illusion)
- Often enough for “binary search debugging”
- Also useful for learning program structure (e.g., when is some function called)
- Skim the manual for other features.

A few tricks

- Everyone develops their own “debugging tricks”; here are a few:
 - Always checking why a seg-fault happened (infinite stack and array-overflow very different)
 - Printing pointer values to see how big objects were.
 - “Staring at code” even if it does not crash
 - Printing array contents (especially last elements)
 - . . .

Advice

- Understand what the tool provides you
- Use it to accomplish a task, for example “I want to know the call-stack when I get the NULL-pointer dereference”
- Optimize your time developing software
 - Think of debugging as a systematic experiment to discover what’s wrong — not a way to randomly poke around. Observation: the problem; hypothesis: I think the cause is ...; experiment: use debugger to verify
- Use development environments that have debuggers?
- See also: jdb for Java
- Like any tool, takes extra time at first but designed to save you time in the long run
 - Education is an investment

gdb summary – running programs

- Be sure to compile with `gcc -g`
- Open the program with: `gdb executable_file`
- Start or restart the program: `run program_args`
- Quit the program: `kill`
- Quit gdb: `quit`
- Reference information: `help`

- Most commands have short abbreviations
- `<return>` often repeats the last command
 - Particularly useful when stepping through code

gdb summary – looking around

- bt – stack backtrace
- up, down – change current stack frame
- list – display source code (list n, list *function_name*)
- print expression – evaluate and print expression
- display expression – (re-)evaluate and print expression every time execution pauses.
 - undisplay – remove an expression from this recurring list.
- info locals – print all locals (but not parameters)
- x (examine) – look at blocks of memory in various formats

gdb summary – breakpoints, stepping

- `break` – set breakpoint. (`break function_name`, `break linenumber`, `break file:linenumber`)
- `info break` – print table of currently set breakpoints
- `clear` – remove breakpoints
- `disable/enable` – temporarily turn breakpoints off/on without removing them from the breakpoint table

- `continue` – resume execution to next breakpoint or end of program
- `step` – execute next source line
- `next` – execute next source line, but treat function calls as a single statement and don't step into them
- `finish` – execute to the conclusion of the current function
 - How to recover if you meant “next” instead of “step”
