## CSE 421

# Approximation Alg 

Shayan Oveis Gharan

## Midterm

Congratulations! You did great in the midterm
Median ~ 70\%

- I did very well in the midterm; so l'll get a 4.0, Yaay! (not really) Final is harder and has a significant impact on your final gpa
- I did terrible in midterm, can I still get 3.9 or 4.0 ? Yes!
- If you are way below median below $50 \%$ (midterm grade <35) try harder
- Will I pass this course, Typically only 4/200 may get below 3.0.

Final will be harder

## Midterm Sample Solutions

Problem 2: Alg: Find a cycle C in G. Let $e=(u, v)$ an edge in C. G-e is a tree, and we can color by 2 colors (proved in class). Use the third color for vertex u.
Correctness: $G$ has $n$ vertices and $n$ edges and connected=> $G$ has a cycle $C$ (section 2), Let $e=(u, v)$ an edge in $C$, G-e is a tree (proved in class). G-e can be colored with 2 colors (proved in class). e is the only non-tree edge and a possible violation so using the third color on v makes sure all adjacent vertices have distinct colors.
P3) Alg: If $G$ has a vertex of deg 0 output no, o.w. output yes Correctness: If G has a deg 0 vertex, that is always a source and sink so impossible. Otherwise, since all vertices has even degree, G can be partitioined into disjoint cycles (homework 2). Every vertex has deg>=2, so shows up in at least one cycle. Orienting every cycle clockwise every vertex will have indegree,outdegree>=1 so not a source nor a sink.

## Possible Wrong answers

Problem 2:

- Delete arbitrary vertex v, color the rest of the graph, then add back $v$ and color $v$ with a color not used on neighbors.
- Choose $v$ with minimum degree, color $v$ with an available color, then delete v and color the rest of the graph

Problem 3:

- Same as HW: Orient all edges of the tree away from the root, orient the rest of the edges arbitrarily.

## Q/A

- HW problems are too hard for me
- We have resources to prepare for HW
- section, $\mathrm{OH}, \ldots$
- Exercises in the book.
- USA Olympiad training website: https://train.usaco.org
- Difficult HW problems prepare you for real world algorithm problems
- Grading rules are too strict
- Every week I spent hours to train TAs how to grade. The well-defined rubric is my effort to have a systematic grading guidelines that all TAs can follow. Without it everybody grades arbitrarily.
- Everything is not about grade! We are here to learn.
- TAs have not responded to my re-grade requests
- TAs are also humans; give them sometime.
- Send me an email or come to OH , l'll look into your request
- What is the point of this course after all? Why do you have to prove correctness of an algorithm?
- Often algorithms that we design are incorrect.

## Approximation Alg Summary

- To design approximation Alg, always find a way to lower bound OPT
- The best known approximation Alg for vertex cover is the greedy.
- It has been open for 50 years to obtain a polynomial time algorithm with approximation ratio better than 2
- The best known approximation Alg for set cover is the greedy.
- It is NP-Complete to obtain better than In n approximation ratio for set cover.

## Dynamic Programming

## Algorithmic Paradigm

Greedy: Build up a solution incrementally, myopically optimizing some local criterion.

Divide-and-conquer: Break up a problem into two sub-problems, solve each sub-problem independently, and combine solution to sub-problems to form solution to original problem.

Dynamic programming. Break up a problem into a series of overlapping sub-problems, and build up solutions to larger and larger sub-problems. Memorize the answers to obtain polynomial time ALG.

## Dynamic Programming History

Bellman. Pioneered the systematic study of dynamic programming in the 1950s.

Etymology.
Dynamic programming = planning over time.
Secretary of Defense was hostile to mathematical research.
Bellman sought an impressive name to avoid confrontation.

- "it's impossible to use dynamic in a pejorative sense"
- "something not even a Congressman could object to"

## Dynamic Programming Applications

## Areas:

- Bioinformatics
- Control Theory
- Information Theory
- Operations Research
- Computer Science: Theory, Graphics, AI, ...

## Some famous DP algorithms

- Viterbi for hidden Markov Model
- Unix diff for comparing two files.
- Smith-Waterman for sequence alignment.
- Bellman-Ford for shortest path routing in networks.
- Cocke-Kasami-Younger for parsing context free grammars.

## Dynamic Programming

Dynamic programming is nothing but algorithm design by induction!

We just "remember" the subproblems that we have solved so far to avoid re-solving the same sub-problem many times.

Weighted Interval Scheduling

## Interval Scheduling

- Job j starts at $s(j)$ and finishes at $f(j)$ and has weight $w_{j}$
- Two jobs compatible if they don't overlap.
- Goal: find maximum weight subset of mutually compatible jobs.

## Unweighted Interval Scheduling: Review

Recall: Greedy algorithm works if all weights are 1:

- Consider jobs in ascending order of finishing time
- Add job to a subset if it is compatible with prev added jobs.

OBS: Greedy ALG fails spectacularly (no approximation ratio) if arbitrary weights are allowed:

by finish

by weight

## Weighted Job Scheduling by Induction

Suppose $1, \ldots, n$ are all jobs. Let us use induction:
IH (strong ind): Suppose we can compute the optimum job scheduling for $<n$ jobs.

IS: Goal: For any n jobs we can compute OPT.
Case 1: Job $n$ is not in OPT.
-- Then, just return OPT of $1, \ldots, n-1$.

Case 2: Job n is in OPT.

-- Then, delete all jobs not compatible with n and recurse.
Q: Are we done?
A: No, How many subproblems are there? Potentially $2^{n}$ all possible subsets of jobs.

## A Bad Example

Consider jobs $\mathrm{n} / 2+1, \ldots, \mathrm{n}$. These decisions have no impact on one another.
How many subproblems do we get?

## Sorting to Reduce Subproblems

IS: For jobs $1, \ldots$, n we want to compute OPT
Sorting Idea: Label jobs by finishing time $f(1) \leq \cdots \leq f(n)$
Case 1: Suppose OPT has job n.

- So, all jobs ithat are not compatible with $n$ are not OPT
- Let $\mathrm{p}(\mathrm{n})=$ largest index $\mathrm{i}<\mathrm{n}$ such that job i is compatible with n .
- Then, we just need to find OPT of $1, \ldots, p(n)$

## Sorting to reduce Subproblems

IS: For jobs $1, \ldots$, n we want to compute OPT
Sorting Idea: Label jobs by finishing time $f(1) \leq \cdots \leq f(n)$
Case 1: Suppose OPT has job n.

- So, all jobs i that are not compatible with n are not OPT
- Let $\mathrm{p}(\mathrm{n})=1$ This is how we differentiate gatible with n .
- Then, from solving Maximum Independent Set Problem
Case 2: OPTuk
- Then, OPT is just the optimum $1, \ldots, n-1$

Q: Have we made any progress (still reducing to two subproblems)?
A: Yes! This time every subproblem is of the form $1, \ldots, i$ for some $i$ So, at most $n$ possible subproblems.

## Bad Example Review

How many subproblems do we get in this sorted order?

## Weighted Job Scheduling by Induction

Sorting Idea: Label jobs by finishing time $f(1) \leq \cdots \leq f(n)$ To solve OPT(j):
Case 1: OPT(j) has job j

- So, all jobs i that are n
- Let $\mathrm{p}(\mathrm{j})=$ largest index
- So OPT $(j)=O P T(p(j)) \cup\{j\}$.

Case 2: OPT(j) does not select job j.

- Then, $\operatorname{OPT}(j)=O P T(j-1)$

$$
O P T(j)=\left\{\begin{array}{lc}
0 & \text { if } j=0 \\
\max \left(w_{j}+O P T(p(j)), O P T(j-1)\right) & \text { o.w. }
\end{array}\right.
$$

## Algorithm

```
Input: n, s(1),\ldots,s(n) and f(1),\ldots,f(n) and w
Sort jobs by finish times so that f(1)\leqf(2)\leq\cdotsf(n).
Compute p(1),p(2),\ldots,p(n)
Compute-Opt(j) {
    if (j = 0)
        return 0
    else
        return max(wi}+\mathrm{ + Compute-Opt(p(j)), Compute-Opt(j-1))
}
```

## Recursive Algorithm Fails

Even though we have only n subproblems, we do not store the solution to the subproblems
$>$ So, we may re-solve the same problem many many times.
Ex. Number of recursive calls for family of "layered" instances grows like Fibonacci sequence

$p(1)=0, p(j)=j-2$

## Algorithm with Memoization

Memoization. Compute and Store the solution of each sub-problem in a cache the first time that you face it. lookup as needed.

```
Input: n, s(1),\ldots,s(n) and f(1),\ldots,f(n) and w, w, w,
Sort jobs by finish times so that f(1) \leqf(2)\leq\cdotsf(n).
Compute p(1),p(2),\ldots,p(n)
for j = 1 to n
    M[j] = empty
M[0] = 0
M-Compute-Opt(j) {
    if (M[j] is empty)
        M[j] = max(wicm-Mompute-Opt(p(j)), M-Compute-Opt(j-1))
    return M[j]
}
```

## Bottom up Dynamic Programming

You can also avoid recusion

- recursion may be easier conceptually when you use induction

```
Input: n, s(1),\ldots,s(n) and f(1),\ldots,f(n) and wi,\ldots,wn.
Sort jobs by finish times so that f(1) \leqf(2)\leq\cdotsf(n).
Compute p(1),p(2),\ldots,p(n)
Iterative-Compute-Opt {
    M[0] = 0
    for j = 1 to n
        M[j] = max(wj + M[p(j)], M[j-1])
}
Output M[n]
```

Claim: $\mathrm{M}[\mathrm{j}]$ is value of $\mathrm{OPT}(\mathrm{j})$
Timing: Easy. Main loop is $\mathrm{O}(\mathrm{n})$; sorting is $\mathrm{O}(\mathrm{n} \log \mathrm{n})$

## Example

Label jobs by finishing time: $f(1) \leq \cdots \leq f(n)$.
$\mathrm{p}(\mathrm{j})=$ largest index $\mathrm{i}<\mathrm{j}$ such that job i is compatible with j .

## Example

Label jobs by finishing time: $f(1) \leq \cdots \leq f(n)$.
$\mathrm{p}(\mathrm{j})=$ largest index $\mathrm{i}<\mathrm{j}$ such that job i is compatible with j .

## Example

Label jobs by finishing time: $f(1) \leq \cdots \leq f(n)$.
$\mathrm{p}(\mathrm{j})=$ largest index $\mathrm{i}<\mathrm{j}$ such that job i is compatible with j .

## Example
