- Project 2 extension: Friday, Feb 8
- Project 2 help session: today at 5:30 in Sieg 327

Projective geometry

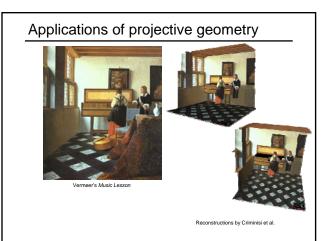

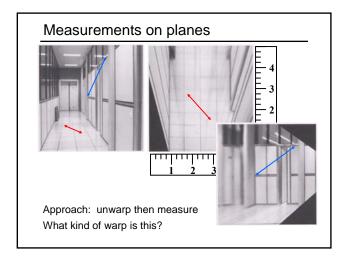

Readings • Mundy, J.L. and Zisserman, A., Geometric Invariance in Computer Vision, Appendix: Projective Geometry for Machine Vision, MIT Press, Cambridge, MA, 1992, (read 23.1 - 23.5, 23.10) – available online: <u>http://www.cs.cmu.edu/-ph/869/papers/zisser-mundy.pdf</u>

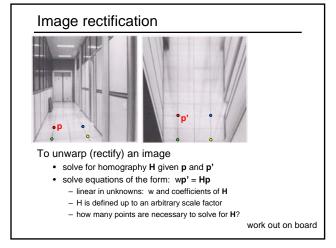

Projective geometry—what's it good for?

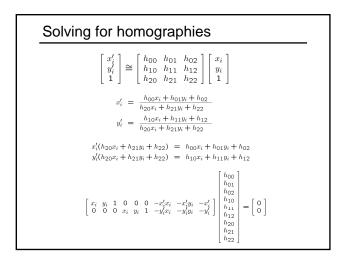

Uses of projective geometry

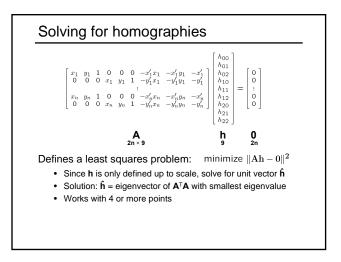

- Drawing
- Measurements
- Mathematics for projection
- Undistorting images
- Focus of expansion
- Camera pose estimation, match move
- Object recognition

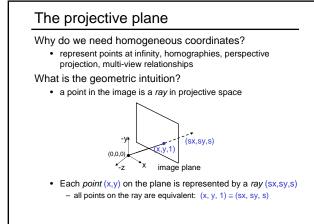

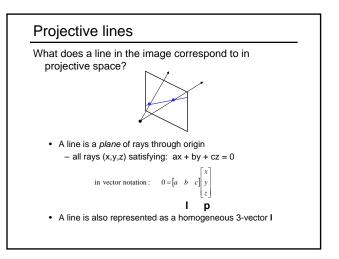

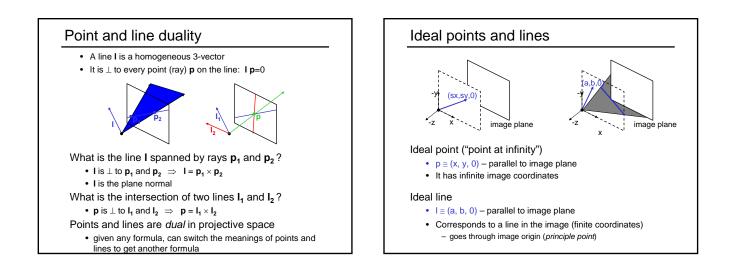

Homographies of points and lines

Computed by 3x3 matrix multiplication

- To transform a point: p' = Hp
- To transform a line: $lp=0 \rightarrow l'p'=0$
 - $0 = \mathbf{I}\mathbf{p} = \mathbf{I}\mathbf{H}^{-1}\mathbf{H}\mathbf{p} = \mathbf{I}\mathbf{H}^{-1}\mathbf{p}^{\prime} \Rightarrow \mathbf{I}^{\prime} = \mathbf{I}\mathbf{H}^{-1}$
 - lines are transformed by postmultiplication of H-1

3D projective geometry

These concepts generalize naturally to 3D

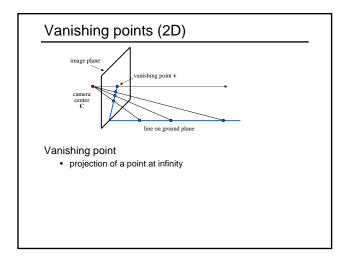

- Homogeneous coordinates
- Projective 3D points have four coords: P = (X,Y,Z,W)
 Duality
 - A plane N is also represented by a 4-vector
 - Points and planes are dual in 3D: N P=0
- Projective transformations
- Represented by 4x4 matrices T: P' = TP, N' = N T⁻¹

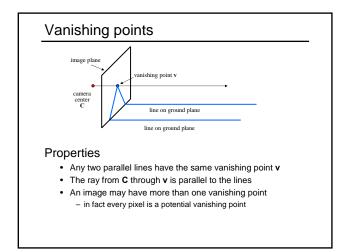

3D to 2D: "perspective" projection

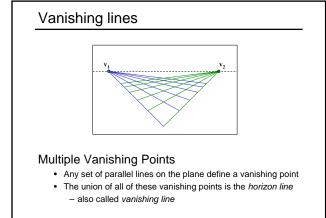

Matrix Projection: $\mathbf{p} = \begin{bmatrix} wx \\ wy \\ w \end{bmatrix} = \begin{bmatrix} * & * & * \\ * & * & * \\ * & * & * \end{bmatrix} \begin{bmatrix} X \\ Y \\ z \\ 1 \end{bmatrix} = \mathbf{\Pi} \mathbf{P}$

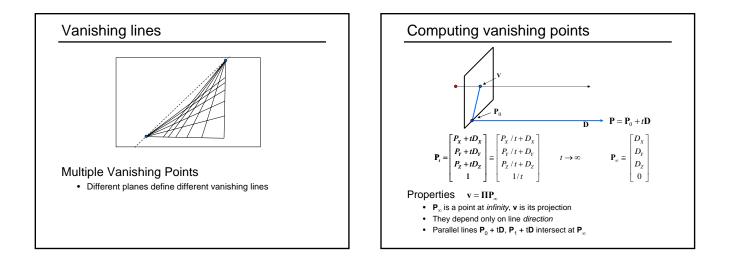

What is not preserved under perspective projection?

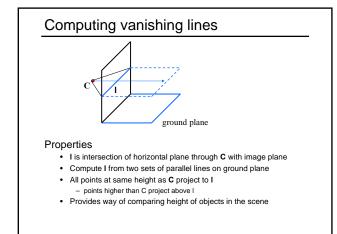

What IS preserved?

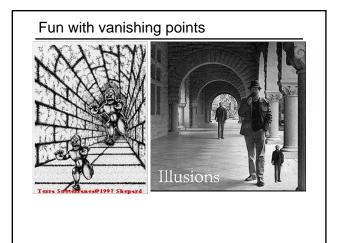

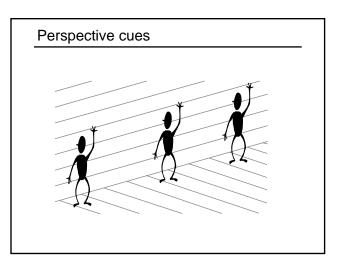

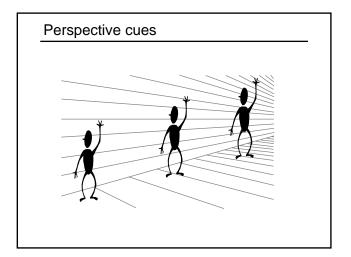

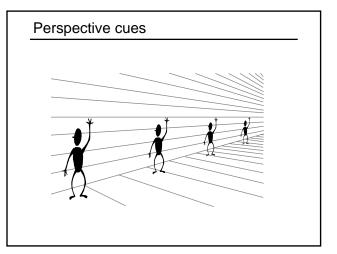

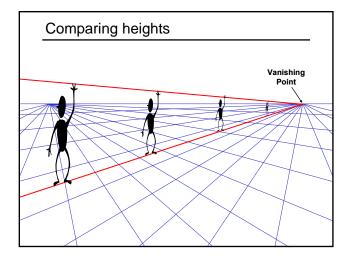

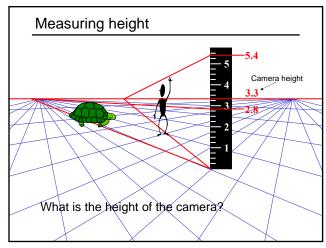

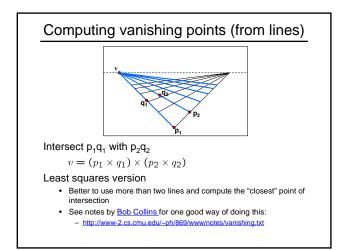

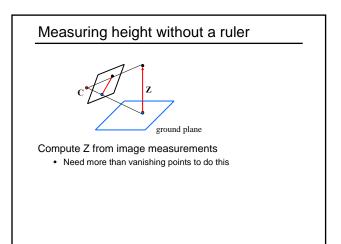

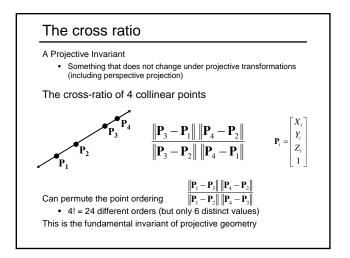

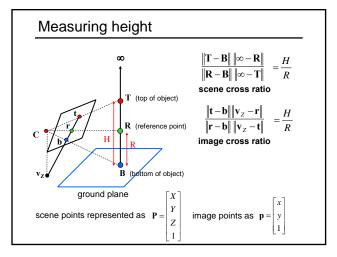

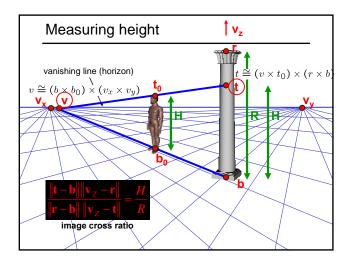

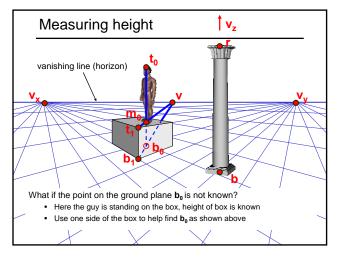

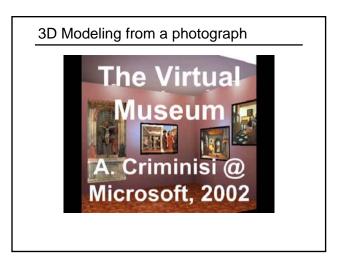

Computing (X,Y,Z) coordinates

Okay, we know how to compute height (Z coords) • how can we compute X, Y?

Camera calibration

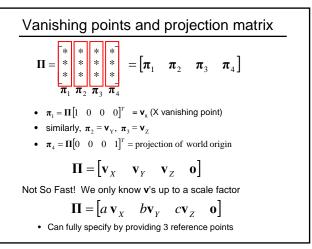

Goal: estimate the camera parameters • Version 1: solve for projection matrix

$$\mathbf{X} = \begin{bmatrix} wx \\ wy \\ w \end{bmatrix} = \begin{bmatrix} * & * & * \\ * & * & * \\ * & * & * \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \\ 1 \end{bmatrix} = \mathbf{\Pi} \mathbf{X}$$

· Version 2: solve for camera parameters separately - intrinsics (focal length, principle point, pixel size)

- extrinsics (rotation angles, translation)

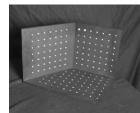

- radial distortion

Calibration using a reference object

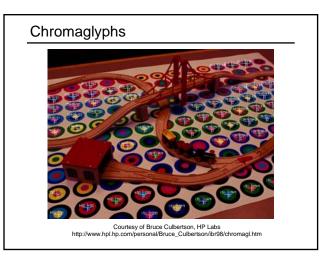

Place a known object in the scene

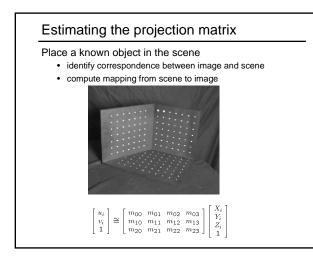

- · identify correspondence between image and scene
- compute mapping from scene to image

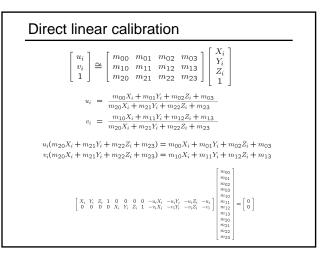

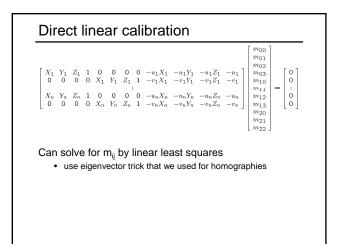

Issues

- must know geometry very accurately
 must know 3D->2D correspondence

Direct linear calibration

Advantage:

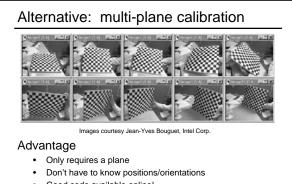

· Very simple to formulate and solve

Disadvantages:

- Doesn't tell you the camera parameters
- Doesn't model radial distortion
- Hard to impose constraints (e.g., known focal length)
- Doesn't minimize the right error function

For these reasons, nonlinear methods are preferred

- Define error function E between projected 3D points and image positions
 E is nonlinear function of intrinsics, extrinsics, radial distortion
- Minimize E using nonlinear optimization techniques
- e.g., variants of Newton's method (e.g., Levenberg Marquart)

- Good code available online!
 - Intel's OpenCV library: http://www.intel.com/research/mrl/research/opencv/
 - Matlab version by Jean-Yves Bouget: <u>http://www.vision.caltech.edu/bougueti/calib_doc/index.html</u>
 - Zhengyou Zhang's web site: <u>http://research.microsoft.com/~zhang/Calib/</u>
