# **CSE/EE 461 – Lecture 12 IP Addressing This Lecture** • Focus - How do we make routing scale? Application Presentation • IP Addressing Session - Hierarchy (prefixes, class A, B, C, subnets) Transport - Also allocation (DHCP, ARP) Data Link Physical sdg // CSE/EE 461, Autumn 2005 L12.2 **Scalability Concerns** • Routing burden grows with size of an internetwork Size of routing tablesVolume of routing messages - Amount of routing computation • To scale to the size of the Internet, apply: - Hierarchical addressing - Use of structural hierarchy - Route aggregation sdg // CSE/EE 461, Autumn 2005 L12.3

#### **IP Addresses**

- Reflect location in topology; used for scalable routing
  - Unlike "flat" Ethernet addresses
- Interfaces on same network share prefix
  - Prefix administratively assigned (IANA or ISP)
  - Addresses globally unique
- Routing only advertises entire networks by prefix
  - Local delivery in a single "network" doesn't involve router
  - (will make "network" precise later on)

sdg // CSE/EE 461, Autumn 2005

L12.4

## Getting an IP address

- Old fashioned way: sysadmin configured each machine
- Dynamic Host Configuration Protocol (DHCP)
  - One DHCP server with the bootstrap info
    - Host address, gateway address, subnet mask, ...
       Find it using broadcast
  - Addresses may be leased; renew periodically
- "Stateless" Autoconfiguration (in IPv6)
  - Get rid of server reuse Ethernet addresses for lower portion of address (uniqueness) and learn higher portion from routers

sdg // CSE/EE 461, Autumn 2005

L12.5

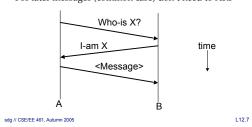

# Address Resolution Protocol (ARP)

- On a single link, need Ethernet addresses to send a frame
  - ... source is a given, but what about destination?
  - Requires mapping from IP to MAC addresses
- ARP is a dynamic approach to learn mapping
  - Node A sends broadcast query for IP address X
  - Node B with IP address X replies with its MAC address M
  - A caches (X, M); old information is timed out (~15 mins)
  - Also: B caches A's MAC and IP addresses, other nodes refresh

sdg // CSE/EE 461, Autumn 2005

## **ARP Example**

- To send first message use ARP to learn MAC address
- For later messages (common case) don't need to ARP

## **IPv4 Address Formats**

 $\bullet \;\;$  32 bits written in "dotted quad" notation, e.g., 18.31.0.135

sdg // CSE/EE 461, Autumn 2005

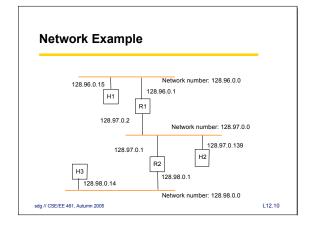

L12.8

#### **IPv6 Address Format**

- 128 bits written in 16 bit hexadecimal chunks
- Still hierarchical, just more levels

sdg // CSE/EE 461, Autumn 2005

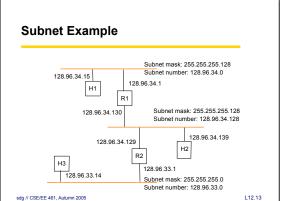

## **Updated Forwarding Routine**

- Used to be "look up destination address for next hop"
- Now addresses have network and host portions:
  - If host: if destination network is the same as the host network, then deliver locally (without router). Otherwise send to the router
  - If router: look up destination network in routing table to find next hop and send to next router. If destination network is directly attached then deliver locally.
- (Note that it will get a little more complicated later)

sdg // CSE/EE 461, Autumn 2005

L12.11

#### **Subnetting – More Hierarchy** Split up one network number into multiple physical networks Network number Host number Class B address • Helps allocation efficiency -- can hand out subnets 1111111111111111111111111 00000000 Subnet mask (255.255.255.0) Rest of internet does not see subnet not see subnet structure - subnet is purely internal to network - aggregates routing info Network number Subnet ID Host ID Subnetted address L12.12 sdg // CSE/EE 461, Autumn 2005

## **Updated Forwarding Routine**

- Used to know network from address (class A, B, C)
- Now need to "search" routing table for right subnet
  - If host: easy, just substitute "subnet" for "network"
  - If router: search routing table for the subnet that the destination belongs to, and use that to forward as before
- $\bullet\,$  (Note that it will get a little more complicated later :)

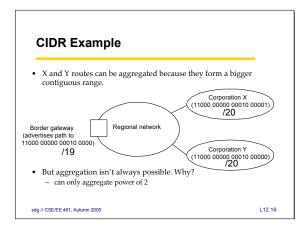

sdg // CSE/EE 461, Autumn 2005

L12.14

# CIDR (Supernetting)

- CIDR = Classless Inter-Domain Routing
- Generalize class A, B, C into prefixes of arbitrary length; now must carry prefix length with address
- Aggregate adjacent advertised network routes
  - e.g., ISP has class C addresses 192.4.16 through 192.4.31
  - Really like one larger 20 bit address class ...
  - Advertise as such (network number, prefix length)
  - Reduces size of routing tables
- But IP forwarding is more involved
  - Based on Longest Matching Prefix operation

sdg // CSE/EE 461, Autumn 2005

## **IP Forwarding Revisited**

- Routing table now contains routes to "prefixes"
  - IP address and length indicating what bits are fixed
- Now need to "search" routing table for longest matching prefix, only at routers
  - Search routing table for the prefix that the destination belongs to, and use that to forward as before
  - There can be multiple matches; take the longest prefix
- This is the IP forwarding routine used at routers.

sdg // CSE/EE 461, Autumn 2005

L12.17

# **Key Concepts**

- Hierarchical address allocation helps routing scale
  - Addresses are constrained by topology
  - Only need to advertise and compute routes for networks
  - Hide internal structure within a domain via subnets
  - Keep host simple and let routers worry about routing
- $\bullet\;$  ARP learns the mapping from IP to MAC address

sdg // CSE/EE 461, Autumn 2005
