## Lecture 18 — Existential Types

Zach Tatlock  
2016

### Abstract Types

Define an interface such that well-typed list-clients cannot break the list-library abstraction

- ▶ Hide the concrete definition of type `mylist`

Why?

- ▶ So clients cannot “forge” lists — always created by library
- ▶ So clients cannot rely on the concrete implementation, which lets us change the library in ways that we *know* will not break clients

To simplify the discussion very slightly, consider just `myintlist`

- ▶ `mylist` is a *type constructor*, a function that given a type gives a type

### Back to our goal

Understand this interface and its nice properties:

```

type 'a mylist;
val mt_list : 'a mylist
val cons    : 'a -> 'a mylist -> 'a mylist
val decons  : 'a mylist -> (('a * 'a mylist) option)
val length  : 'a mylist -> int
val map     : ('a -> 'b) -> 'a mylist -> 'b mylist

```

So far, we can do it *if we expose the definition of* `mylist`

```

mt_list : ∀α.μβ.unit + (α * β)
cons : ∀α.α → (μβ.unit + (α * β)) → (μβ.unit + (α * β))
...

```

### The Type-Application Approach

We can hide `myintlist` via type abstraction (like we hid file-handles):

$$(\Lambda\alpha. \lambda x:\tau_1. \text{list\_client}) [\tau_2] \text{list\_library}$$

where:

- ▶  $\tau_1$  is  $\{ \text{mt} : \alpha, \text{cons} : \text{int} \rightarrow \alpha \rightarrow \alpha, \text{decons} : \alpha \rightarrow \text{unit} + (\text{int} * \alpha), \dots \}$
- ▶  $\tau_2$  is  $\mu\beta.\text{unit} + (\text{int} * \beta)$
- ▶ *list\_client* projects from record  $x$  to get list functions
- ▶ *list\_library* is the record of list functions

## Evaluating ADT via Type Application

$(\Lambda\alpha. \lambda x:\tau_1. list\_client) [\tau_2] list\_library$

Plus:

- ▶ Effective
- ▶ Straightforward use of System F

Minus:

- ▶ The library does not say `myintlist` should be abstract
  - ▶ It relies on clients to abstract it
  - ▶ Can be “fixed” with a “structure inversion” (passing client to the library), but cure arguably worse than disease
- ▶ Different list-libraries have different types, so can’t choose one at run-time or put them in a data structure:
  - ▶ if `n>10` then `hashset_lib` else `listset_lib`
  - ▶ Wish: values *produced* by different libraries must have *different* types, but *libraries* can have the *same* type

## The OO Approach

Use recursive types and records:

```
mt_list :  $\mu\beta. \{ \text{cons} : \text{int} \rightarrow \beta,$   
              $\text{decons} : \text{unit} \rightarrow (\text{unit} + (\text{int} * \beta)),$   
             ... }
```

`mt_list` is an *object* — a record of functions plus private data

The `cons` field holds a function that returns a new record of functions

Implementation uses recursion and “hidden fields” in an essential way

- ▶ In ML, free variables are the “hidden fields”
- ▶ In OO, private fields or abstract interfaces “hide fields”

(See Caml code for a slightly different example)

## Evaluating the Closure/OO Approach

Plus:

- ▶ It works in popular languages (no explicit type variables)
- ▶ Different list-libraries have the same type

Minus:

- ▶ Changed the interface (no big deal?)
- ▶ Fails on “strong” binary ( $(n > 1)$ -ary) operations
  - ▶ Have to write `append` in terms of `cons` and `decons`
  - ▶ Can be *impossible*  
(silly example: see type `t2` in ML file)

## The Existential Approach

Achieved our goal two different ways, but each had drawbacks

There is a direct way to model ADTs that captures their essence quite nicely: types of the form  $\exists\alpha.\tau$

Next slide has a formalization, but we’ll mostly focus on

- ▶ The intuition
- ▶ How to use the idea to *encode* closures (e.g., for callbacks)

Why don’t many real PLs have existential types?

- ▶ Because other approaches kinda work?
- ▶ Because modules work well even if “second-class”?
- ▶ Because have only been well-understood since the mid-1980s and “tech transfer” takes forever and a day?

## Existential Types

$e ::= \dots \mid \text{pack } \tau, e \text{ as } \exists \alpha. \tau \mid \text{unpack } e \text{ as } \alpha, x \text{ in } e$   
 $v ::= \dots \mid \text{pack } \tau, v \text{ as } \exists \alpha. \tau$   
 $\tau ::= \dots \mid \exists \alpha. \tau$

$$\frac{e \rightarrow e'}{\text{pack } \tau_1, e \text{ as } \exists \alpha. \tau_2 \rightarrow \text{pack } \tau_1, e' \text{ as } \exists \alpha. \tau_2}$$

$$\frac{e \rightarrow e'}{\text{unpack } e \text{ as } \alpha, x \text{ in } e_2 \rightarrow \text{unpack } e' \text{ as } \alpha, x \text{ in } e_2}$$

$$\frac{}{\text{unpack } (\text{pack } \tau_1, v \text{ as } \exists \alpha. \tau_2) \text{ as } \alpha, x \text{ in } e_2 \rightarrow e_2[\tau_1/\alpha][v/x]}$$

$$\frac{\Delta; \Gamma \vdash e : \tau'[\tau/\alpha]}{\Delta; \Gamma \vdash \text{pack } \tau, e \text{ as } \exists \alpha. \tau' : \exists \alpha. \tau'}$$

$$\frac{\Delta; \Gamma \vdash e_1 : \exists \alpha. \tau' \quad \Delta, \alpha; \Gamma, x:\tau' \vdash e_2 : \tau \quad \Delta \vdash \tau \quad \alpha \notin \Delta}{\Delta; \Gamma \vdash \text{unpack } e_1 \text{ as } \alpha, x \text{ in } e_2 : \tau}$$

## List library with $\exists$

The list library is an existential package:

```

pack ( $\mu\alpha.$ unit + (int *  $\alpha$ )), list_library as
 $\exists\beta.$  { empty :  $\beta$ ,
      cons : int  $\rightarrow$   $\beta \rightarrow \beta$ ,
      decons :  $\beta \rightarrow$  unit + (int *  $\beta$ ),
      ... }
    
```

Another library would “pack” a *different* type and implementation, but have the *same* overall type

Binary operations work fine, e.g., **append** :  $\beta \rightarrow \beta \rightarrow \beta$

Libraries are first-class, but a *use* of a library must be in a scope that “remembers which  $\beta$ ” describes data from that library

- ▶ (If use two libraries in same scope, can’t pass the result of one’s **cons** to the other’s **decons** because the two libraries will use *different* type variables)

## Closures and Existentials

There’s a deep connection between existential types and how closures are used/compiled

- ▶ “Call-backs” are the canonical example

Caml:

- ▶ Interface:

```
val onKeyEvent : (int -> unit) -> unit
```

- ▶ Implementation:

```

let callBacks : (int -> unit) list ref = ref []
let onKeyEvent f = callBacks := f::(!callBacks)
let keyPress i = List.iter (fun f -> f i) !callBacks
    
```

Each registered function can have a different *environment* (free variables of different types), yet every function has type int->unit

## Closures and Existentials

C:

```
typedef struct {void* env; void (*f)(void*,int);} * cb_t;
```

- ▶ Interface: void onKeyEvent(cb\_t);
- ▶ Implementation (assuming a list library):

```

list_t callBacks = NULL;
void onKeyEvent(cb_t cb){callBacks=cons(cb,callBacks)
void keyPress(int i) {
    for(list_t lst=callBacks; lst; lst=lst->tl)
        lst->hd->f(lst->hd->env, i);
}
    
```

Standard problems using subtyping ( $t \leq \text{void}^*$ ) instead of  $\alpha$ :

- ▶ Client must provide an f that downcasts argument back to  $t^*$
- ▶ Typechecker lets library pass any void\* to f

## Closures and Existentials

A type-safe variant of C could have  $\exists\alpha.\tau$  and let programmers code up closures:

```
typedef struct {<a> 'a env; void (*f)('a,int);} * cb_t;
```

- ▶ Interface: `void onKeyEvent(cb_t);`
- ▶ Implementation (assuming a list library):

```
list_t<cb_t> callBacks = NULL;
void onKeyEvent(cb_t cb){callBacks=cons(cb,callBacks)
void keyPress(int i) {
    for(list_t<cb_t> lst=callBacks; lst; lst=lst->t1)
        let {<a> x, y} = *lst->hd; // pattern-match
        y(x,i); // no other argument to y typechecks!
    }
}
```

Not shown: To create a `cb_t`, the “the types must match up”
