Gene Prediction

Gene Finding: Motivation

Sequence data flooding in

What does it mean?

protein genes, RNA genes, mitochondria, chloroplast, regulation, replication, structure, repeats, transposons, unknown stuff, …

More generally, how do you learn from complex data in an unknown language

Protein Coding Nuclear DNA

Focus of this lecture

Goal: Automated annotation of new seq data

State of the Art:

- In Eukaryotes:
  - predictions ~ 60% similar to real proteins
  - ~80% if database similarity used
- Prokaryotes
  - better, but still imperfect
- Lab verification still needed, still expensive
- Largely done for Human; unlikely for most others

Biological Basics

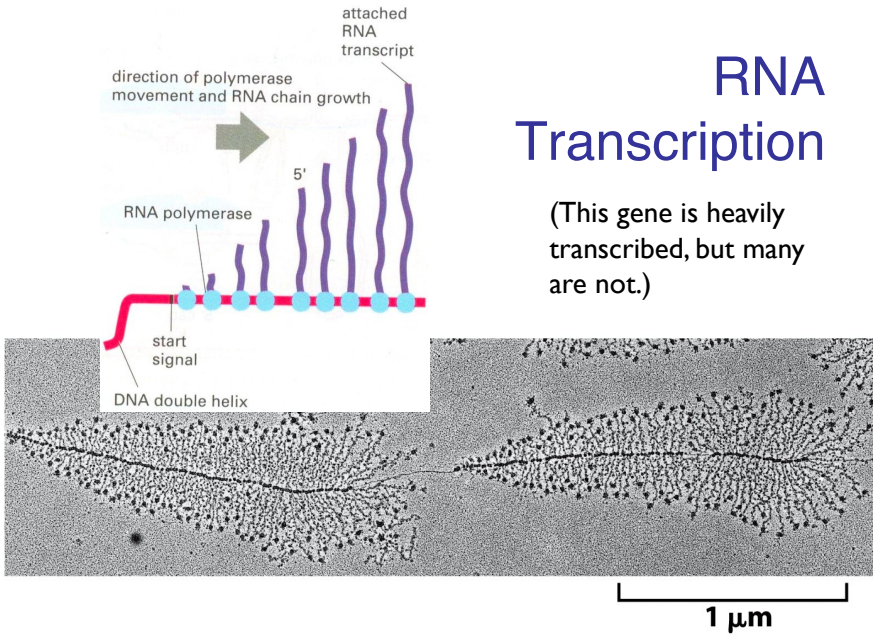
Central Dogma:

DNA —transcription→ RNA —translation→ Protein

Codons: 3 bases code one amino acid

- Start codon
- Stop codons
- 3', 5' Untranslated Regions (UTR's)

RNA Transcription



(This gene is heavily transcribed, but many are not.)

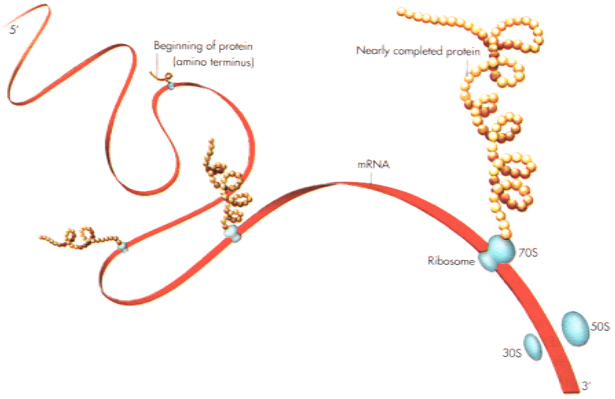
Figure 6-9 Molecular Biology of the Cell 5/e (© Garland Science 2008)

Codons & The Genetic Code

First Base	Second Base U	Second Base C	Second Base A	Second Base G	Third Base
U	Phe	Ser	Tyr	Cys	U
	Phe	Ser	Tyr	Cys	C
	Leu	Ser	Stop	Stop	A
	Leu	Ser	Stop	Trp	G
C	Leu	Pro	His	Arg	U
	Leu	Pro	His	Arg	C
	Leu	Pro	Gln	Arg	A
	Leu	Pro	Gln	Arg	G
A	Ile	Thr	Asn	Ser	U
	Ile	Thr	Asn	Ser	C
	Ile	Thr	Lys	Arg	A
	Met/Start	Thr	Lys	Arg	G
G	Val	Ala	Asp	Gly	U
	Val	Ala	Asp	Gly	C
	Val	Ala	Glu	Gly	A
	Val	Ala	Glu	Gly	G

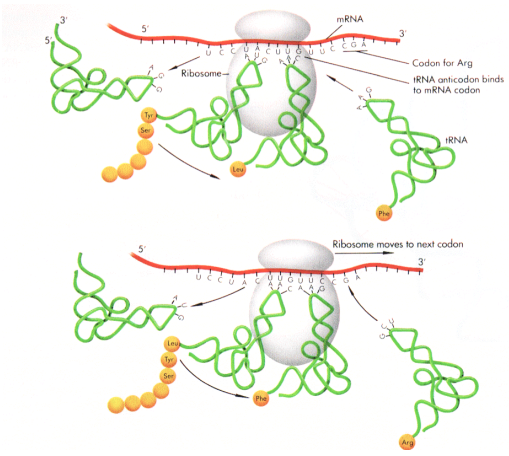
Ala	: Alanine
Arg	: Arginine
Asn	: Asparagine
Asp	: Aspartic acid
Cys	: Cysteine
Gln	: Glutamine
Glu	: Glutamic acid
Gly	: Glycine
His	: Histidine
Ile	: Isoleucine
Leu	: Leucine
Lys	: Lysine
Met	: Methionine
Phe	: Phenylalanine
Pro	: Proline
Ser	: Serine
Thr	: Threonine
Trp	: Tryptophane
Tyr	: Tyrosine
Val	: Valine

Translation: mRNA → Protein



Watson, Gilman, Witkowski, & Zoller, 1992

Ribosomes



Watson, Gilman, Witkowski, & Zoller, 1992

Idea #1: Find Long ORF's

Reading frame: which of the 3 possible sequences of triples does the ribosome read?

Open Reading Frame: No stop codons

In random DNA

- average ORF ~ 64/3 = 21 triplets
- 300bp ORF once per 36kbp per strand

But average protein ~ 1000bp

A Simple ORF finder

start at left end

scan triplet-by-non-overlapping triplet for AUG

then continue scan for STOP

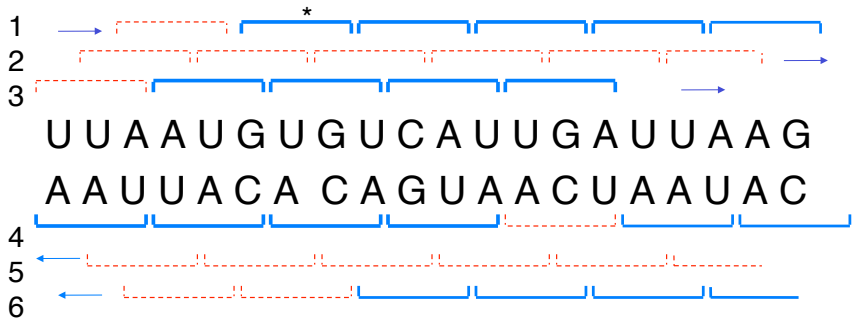
repeat until right end

repeat all starting at offset 1

repeat all starting at offset 2

then do it again on the other strand

Scanning for ORFs



* In bacteria, GUG is sometimes a start codon…

Idea #2: Codon Frequency

In random DNA

- Leucine : Alanine : Tryptophan = 6 : 4 : 1

But in real protein, ratios ~ 6.9 : 6.5 : 1

So, coding DNA is not random

Even more: synonym usage is biased (in a species dependant way)

- examples known with 90% AT 3rd base
  - Why? E.g. efficiency, histone, enhancer, splice interactions

Recognizing Codon Bias

Assume

- Codon usage i.i.d.; *abc* with freq. *f(abc)*
- $a_1a_2a_3a_4\ldots a_{3n+2}$ is coding, unknown frame

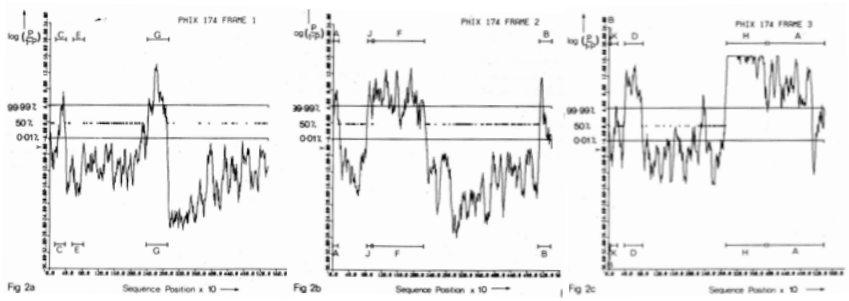
Calculate

- $p_1 = f(a_1a_2a_3)f(a_4a_5a_6)\ldots f(a_{3n-2}a_{3n-1}a_{3n})$
- $p_2 = f(a_2a_3a_4)f(a_5a_6a_7)\ldots f(a_{3n-1}a_{3n}\,a_{3n+1})$
- $p_3 = f(a_3a_4a_5)f(a_6a_7a_8)\ldots f(a_{3n}\,a_{3n+1}a_{3n+2})$
- $P_i = p_i / (p_1+p_1+p_3)$

More generally: *k*-th order Markov model

- *k* = 5 or 6 is typical

Codon Usage in Φx174



Staden & McLachlan, NAR 10, 1 1982, 141-156

Promoters, etc.

In prokaryotes, most DNA coding

- E.g. ~ 70% in *H. influenzae*

Long ORFs + codon stats do well

But obviously won't be perfect

- short genes
- 5' & 3' UTR's

Can improve by modeling promoters, etc.

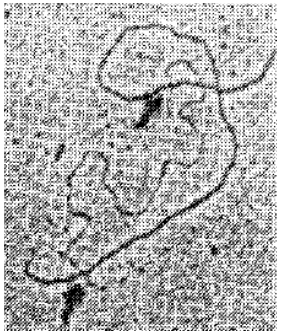
- e.g. via WMM or higher-order Markov models

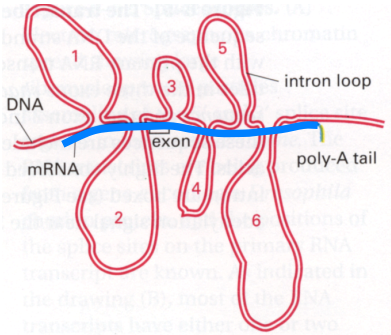
Eukaryotes

As in prokaryotes (but maybe more variable)

- promoters
- start/stop transcription
- start/stop translation

And then…





Nobel Prize of the week: P. Sharp, 1993, Splicing

Mechanical Devices of the Spliceosome: Motors, Clocks, Springs, and Things

Jonathan P. Staley and Christine Guthrie

CELL Volume 92, Issue 3 , 6 February 1998, Pages 315-326

Figure 2. Spliceosome Assembly, Rearrangement, and Disassembly Requires ATP, Numerous DExD/H box Proteins, and Prp24. The snRNPs are depicted as circles. The pathway for *S. cerevisiae* is shown.

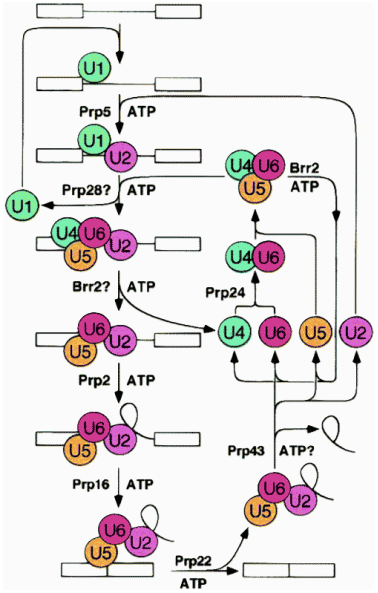


Figure 3. Splicing Requires Numerous Rearrangements

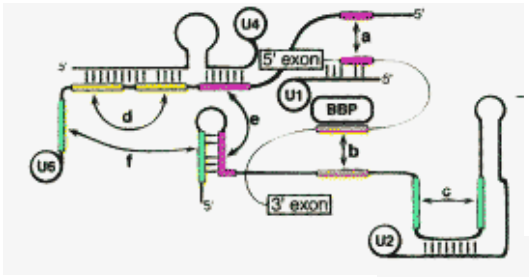
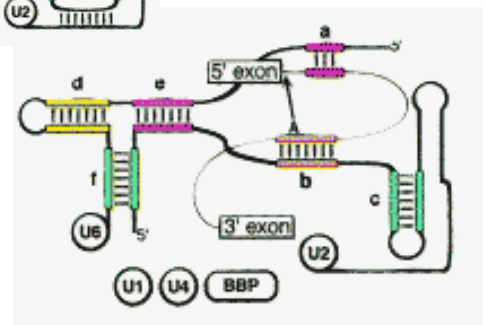


E.g.:
exchange of
U1 for U6



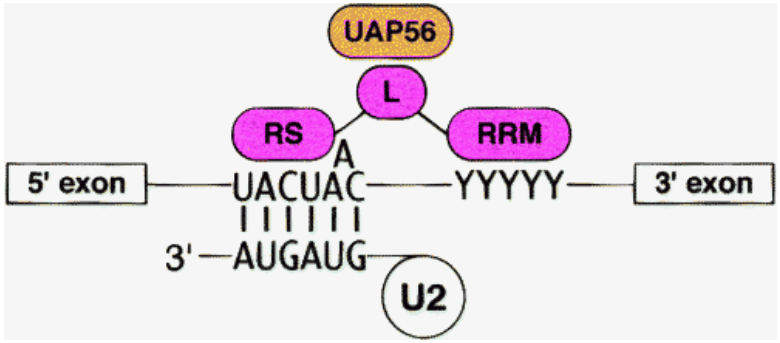


Figure 6. A Paradigm for Unwindase Specificity and Timing? The DExD/H box protein UAP56 (orange) binds U2AF65 (pink) through its linker region (L). U2 binds the branch point. Y's indicate the polypyrimidine stretch; RS, RRM as in Figure 5A. Sequences are from mammals.

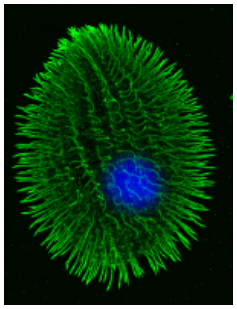
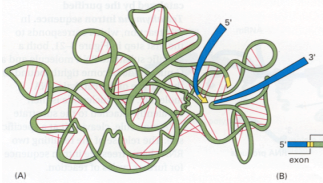
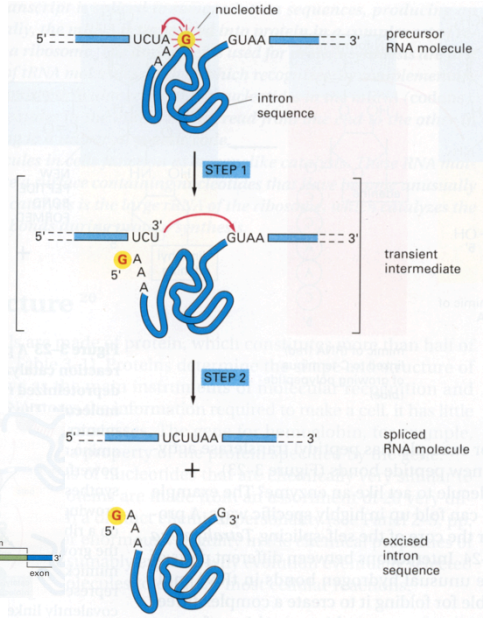
Hints to Origins?



Tetrahymena thermophila

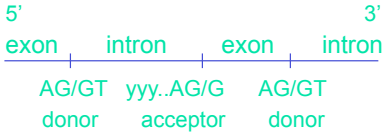




Genes in Eukaryotes

As in prokaryotes (but maybe more variable)
- promoters
- start/stop transcription
- start/stop translation

New Features:
- polyA site/tail
- introns, exons, splicing
- branch point signal
- alternative splicing



Characteristics of human genes

(Nature, 2/2001, Table 21)

	Median	Mean	Sample (size)
Internal exon	122 bp	145 bp	RefSeq alignments to draft genome sequence, with confirmed intron boundaries (43,317 exons)
Exon number	7	8.8	RefSeq alignments to finished seq (3,501 genes)
Introns	1,023 bp	3,365 bp	RefSeq alignments to finished seq (27,238 introns)
3' UTR	400 bp	770 bp	Confirmed by mRNA or EST on chromo 22 (689)
5' UTR	240 bp	300 bp	Confirmed by mRNA or EST on chromo 22 (463)
Coding seq	1,100 bp	1340 bp	Selected RefSeq entries (1,804)*
(CDS)	367 aa	447 aa	
Genomic span	14 kb	27 kb	Selected RefSeq entries (1,804)*

* 1,804 selected RefSeq entries were those with full-length unambiguous alignment to finished sequence

Big Genes

Many genes are over 100 kb long,

Max known: dystrophin gene (DMD), 2.4 Mb.

The variation in the size distribution of coding sequences and exons is less extreme, although there are remarkable outliers.

- The titin gene has the longest currently known coding sequence at 80,780 bp; it also has the largest number of exons (178) and longest single exon (17,106 bp).

RNApol rate: 1.2-2.5 kb/min = >16 hours to transcribe DMD

Nature 2/2001

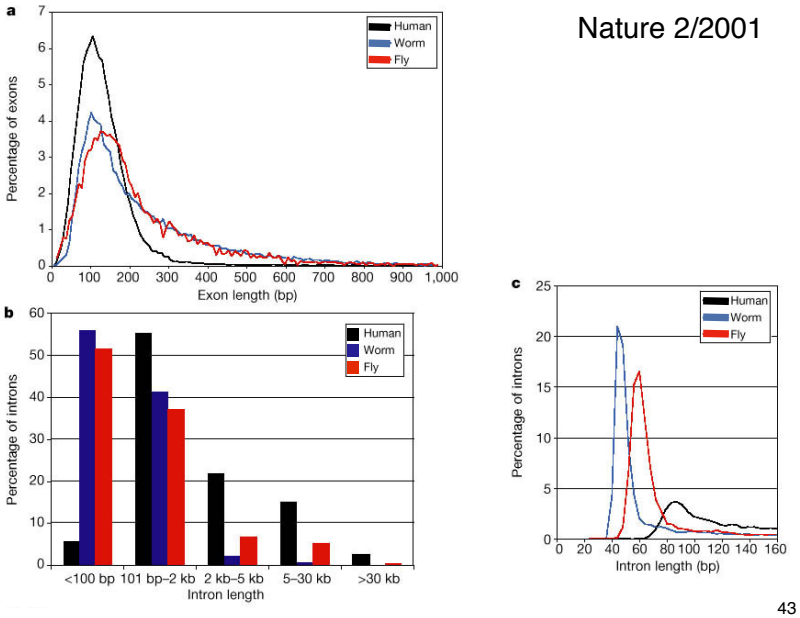


Figure 36 GC content

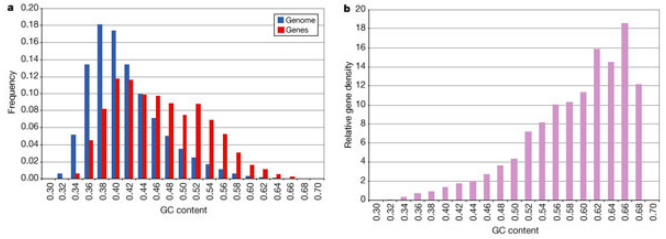
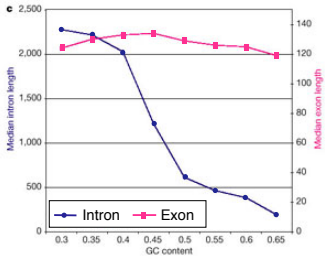
Nature 2/2001



a: Distribution of GC content in genes and in the genome. For 9,315 known genes mapped to the draft genome sequence, the local GC content was calculated in a window covering either the whole alignment or 20,000 bp centered on midpoint of the alignment, whichever was larger. Ns in the sequence were not counted. GC content for the genome was calculated for adjacent nonoverlapping 20,000-bp windows across the sequence. Both distributions normalized to sum to one.



b: Gene density as a function of GC content (= ratios of data in a. Less accurate at high GC because the denominator is small)

c: Dependence of mean exon and intron lengths on GC content. The local GC content, based on alignments to finished sequence only, calculated from windows covering the larger of feature size or 10,000 bp centered on it

Computational Gene Finding?

How do we algorithmically account for all this complexity…

A Case Study -- Genscan

C Burge, S Karlin (1997), "Prediction of complete gene structures in human genomic DNA", Journal of Molecular Biology , 268: 78-94.

Training Data

238 multi-exon genes
142 single-exon genes
total of 1492 exons
total of 1254 introns
total of 2.5 Mb

NO alternate splicing, none > 30kb, ...

Performance Comparison

	Accuracy						
	per nuc.		per exon

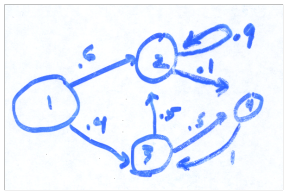
After Burge&Karlin, Table 1. Sensitivity, Sn = TP/AP; Specificity, Sp = TP/PP

Generalized Hidden Markov Models



π: Initial state distribution
a_{ij}: Transition probabilities
One submodel per state
Outputs are *strings* gen'ed by submodel
Given length L
- Pick start state q_1 ($\sim\pi$)
- While $\sum d_i < L$
  - Pick d_i & string s_i of length d_i ~ submodel for q_i
  - Pick next state q_{i+1} ($\sim a_{ij}$)
- Output $s_1 s_2 \ldots$

Decoding

A "parse" ϕ of $s = s_1 s_2 \ldots s_L$ is a pair $d = d_1 d_2 \ldots d_k$, $q = q_1 q_2 \ldots q_k$ with $\sum d_i = L$

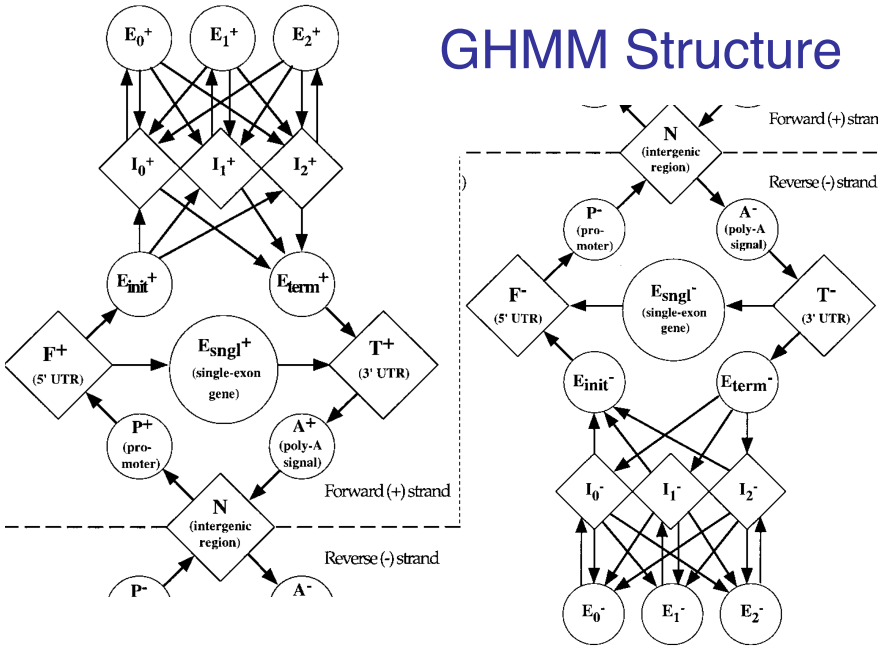
A forward/backward-like alg calculates, e.g.:

Pr(generate $s_1 s_2 \ldots s_i$ & end in state q_k)

(summing over possible predecessor states q_{k-1} and possible d_k, *etc.)*

$$Pr(\phi \mid s) = \frac{Pr(\phi, s)}{Pr(s)} \quad \ldots$$

GHMM Structure



Length Distributions

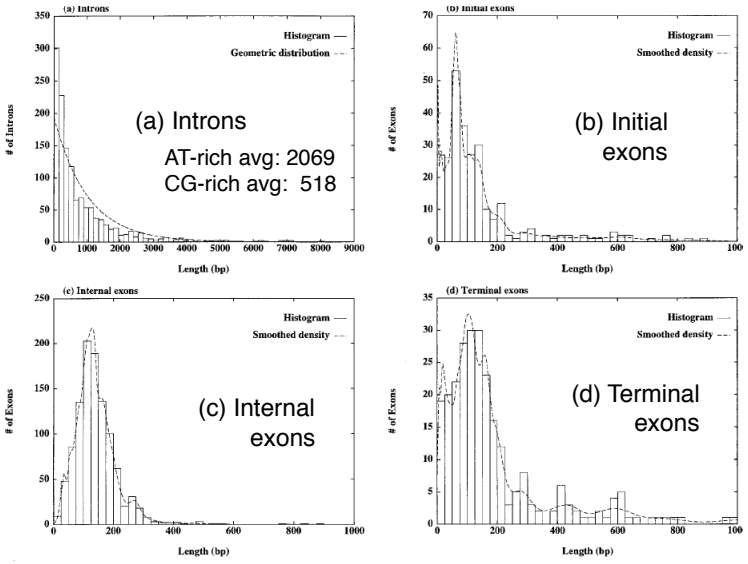


Figure 4. Length distributions are shown for (a) 1254 introns; (b) 238 initial exons; (c) 1151 internal exons; and (d) 238 terminal exons from the 238 multi-exon genes of the learning set $\mathscr{L}$. Histograms (continuous lines) were derived with a bin size of 300 bp in (a), and 25 bp in (b), (c), (d). The broken line in (a) shows a geometric (exponential) distribution with parameters derived from the mean of the intron lengths; broken lines in (b), (c) and (d) are the smoothed empirical distributions of exon lengths used by GENSCAN (details given by Burge, 1997). Note different horizontal and vertical scales are used in (a), (b), (c), (d) and that multimodality in (b) and (d) may, in part, reflect relatively small sample sizes.

Effect of G+C Content

Group	**I**	**II**	**III**	**IV**
C ǂ G% range	<43	43-51	51-57	>57

5' Untranslated region (F+, F-)	0.008	0.018	0.077	0.122
3' Untranslated region (T+, T-)	0.005	0.011	0.045	0.072

Submodels

5’ UTR

L ~ geometric(769 bp), s ~ MM(5)

3’ UTR

L ~ geometric(457 bp), s ~ MM(5)

Intergenic

L ~ geometric(GC-dependent), s ~ MM(5)

Introns

L ~ geometric(GC-dependent), s ~ MM(5)

Submodel: Exons

Inhomogenious 3-periodic 5th order Markov models

Separate models for low GC (<43%), high GC

Track “phase” of exons, i.e. reading frame.

Signal Models I: WMM’s

Polyadenylation

6 bp, consensus AATAAA

Translation Start

12 bp, starting 6 bp before start codon

Translation stop

A stop codon, then 3 bp WMM

Signal Models II: more WMM’s

Promoter

70% TATA

15 bp TATA WMM

s ~ null, L ~ Unif(14-20)

8 bp cap signal WMM

30% TATA-less

40 bp null

Signal Models III: W/WAM's

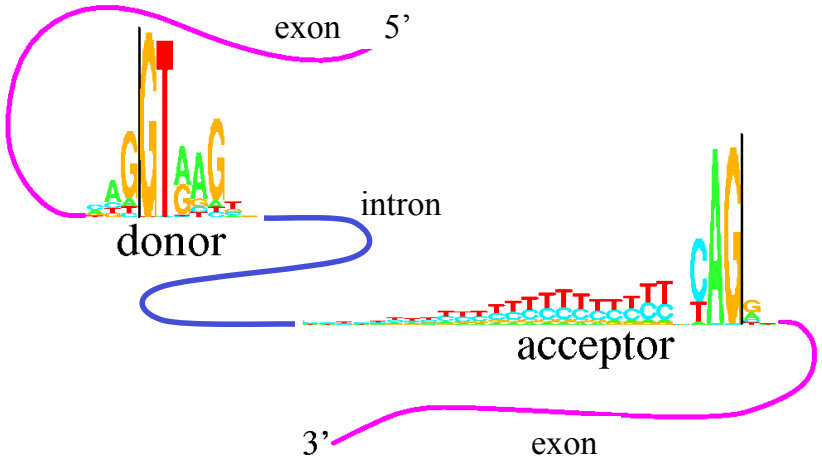
Acceptor Splice Site (3' end of intron)

- [-20..+3] relative to splice site modeled by "1st order weight array model"

Branch point & polypyrimidine tract

- Hard. Even weak consensus like YYRAY found in [-40..-21] in only 30% of training
- "Windowed WAM": 2nd order WAM, but averaged over 5 preceding positions
  "captures weak but detectable tendency toward YYY triplets and certain branch point related triplets like TGA, TAA, …"

What's in the Primary Sequence?



Signal Models IV: Maximum Dependence Decomposition

Donor splice sites (5' end of intron) show dependencies between non-adjacent positions, e.g. poor match at one end compensated by strong match at other end, 6 bp away

Model is basically a decision tree

Uses χ^2 test to quantitate dependence

Are A & B independent ?

	B	not B	
A	8	4	12
not A	2	6	8
	10	10	20

$$\chi^2 = \sum_i \frac{(\text{observed}_i - \text{expcted}_i)^2}{\text{expected}_i}$$

"Expected" means expected assuming independence, e.g. expect B 10/20; A 12/20; both 120/400*20 = 6, etc.

Look up in table (or approximate as normal).

χ^2 test for independence

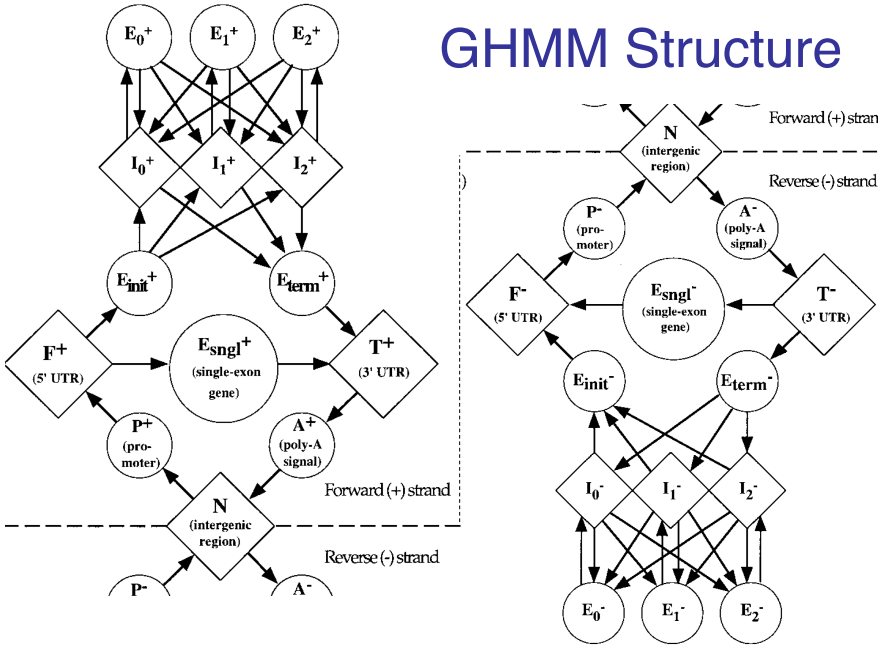
GHMM Structure



Summary of Burge & Karlin

Coding DNA & control signals nonrandom

- Weight matrices, WAMs, etc. for controls
- Codon frequency, etc. for coding

GHMM nice for overall architecture

Careful attention to small details pays

Problems with BK training set

1 gene per sequence

Annotation errors

Single exon genes over-represented?

Highly expressed genes over-represented?

Moderate sized genes over-represented?
(none > 30 kb) …

Similar problems with other training sets, too

Problems with all methods

Pseudo genes

Short ORFs

Sequencing errors

Non-coding RNA genes & spliced UTR's

Overlapping genes

Alternative splicing/polyadenylation

Hard to find novel stuff – not in training

Species-specific weirdness – spliced leaders, polycistronic transcripts, RNA editing…

Other important ideas

Database search - does gene you're predicting look anything like a known protein?

Comparative genomics - what does this region look like in related organisms?
