

# Out-of-Order Execution

Several implementations

- **out-of-order completion**
  - CDC 6600 with **scoreboarding**
  - IBM 360/91 with **Tomasulo's algorithm & reservation stations**
  - out-of-order completion leads to:
    - imprecise interrupts
    - WAR hazards
    - WAW hazards
- **in-order completion**
  - MIPS R10000/R12000 & Alpha 21264/21364 with **large physical register file & register renaming**
  - Intel Pentium Pro/Pentium III with the **reorder buffer**

## Out-of-order Hardware

In order to compute correct results, need to keep track of:

- which instruction is in which stage of the pipeline
- which registers are being used for reading/writing & by which instructions
- which operands are available
- which instructions have completed

Each scheme has different hardware structures & different algorithms to do this

# Tomasulo's Algorithm

## **Tomasulo's Algorithm** (IBM 360/91)

- out-of-order execution capability plus register renaming

## **Motivation**

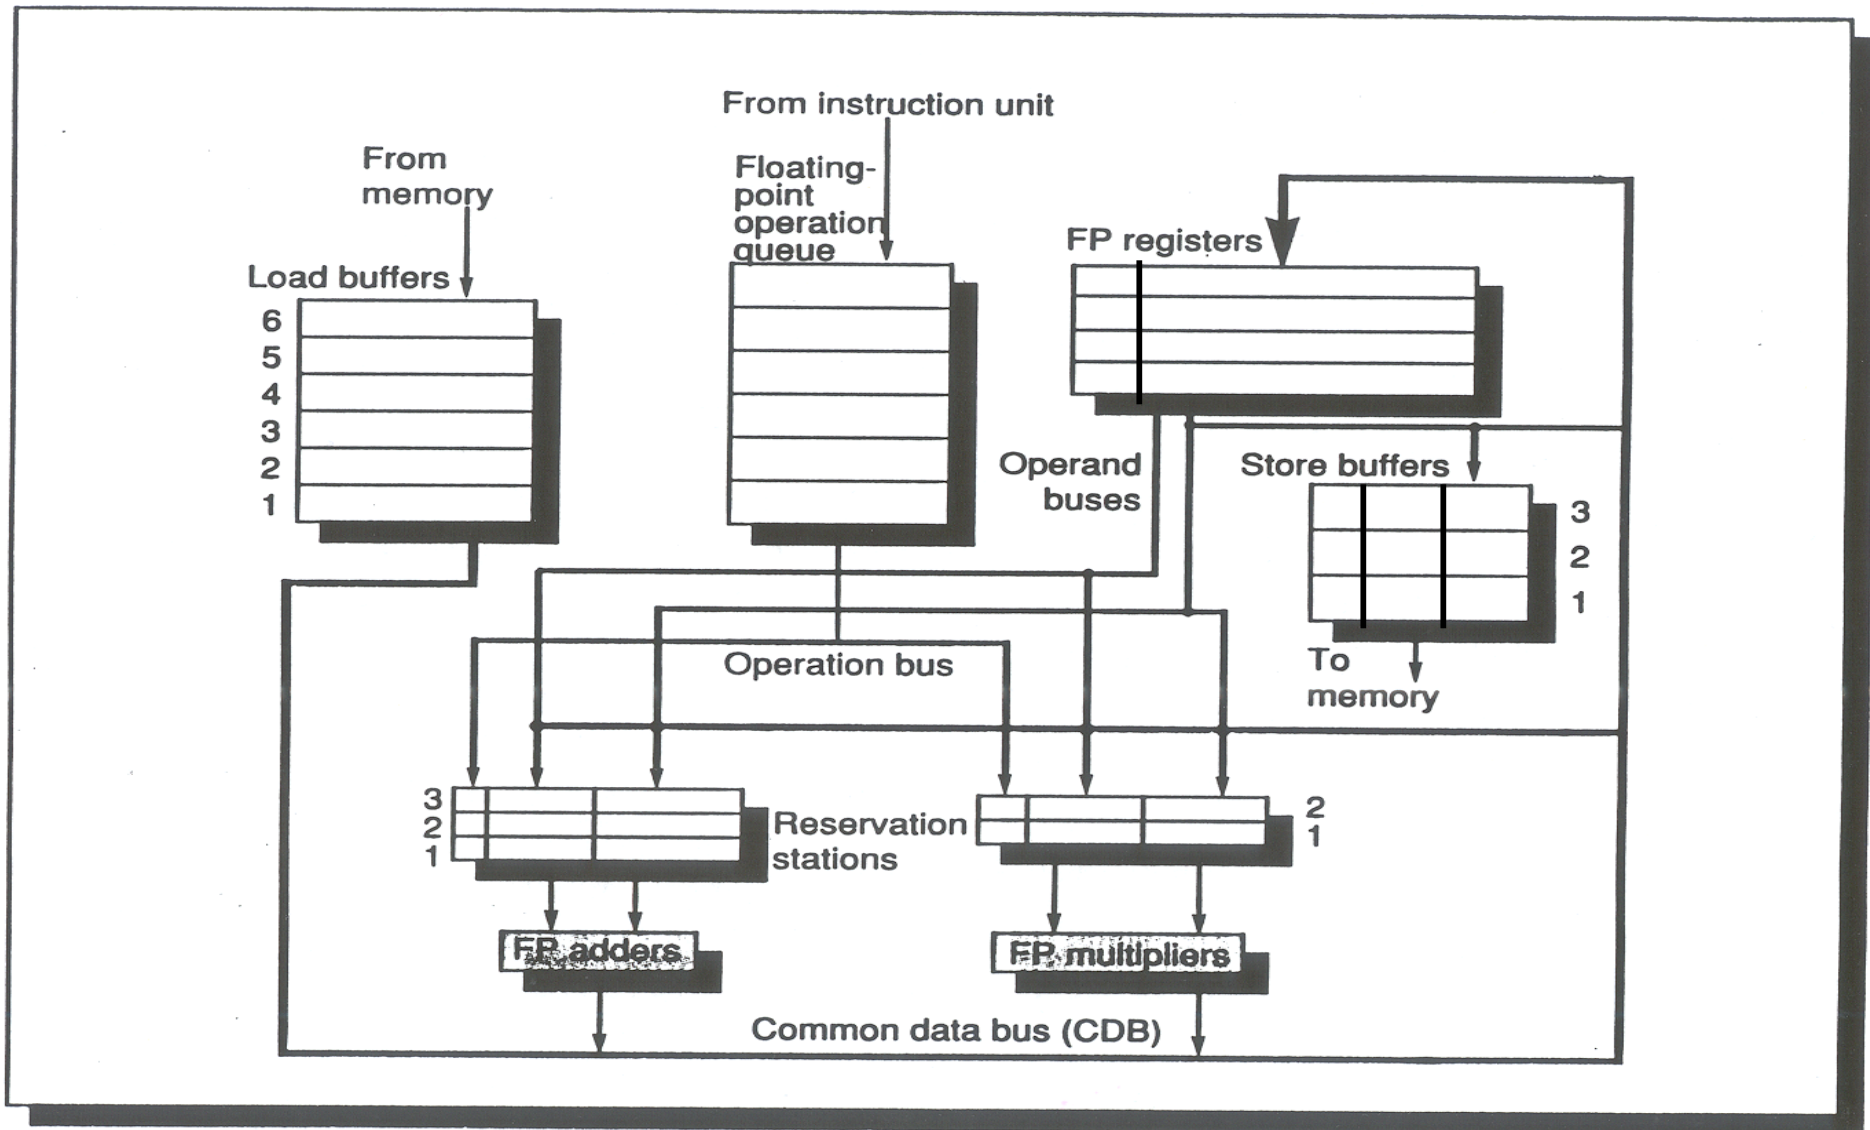

- long FP delays
- only 4 FP registers
- wanted common compiler for all implementations

# Tomasulo's Algorithm

## Key features & hardware structures

- reservation stations
- distributed hazard detection & execution control
  - forwarding to eliminate RAW hazards
  - register renaming to eliminate WAR & WAW hazards
  - deciding which instruction to execute next
- common data bus
- dynamic memory disambiguation

# Hardware for Tomasulo's Algorithm

# Tomasulo's Algorithm: Key Features

## Reservation stations

- buffers for functional units that hold instructions stalled for RAW hazards & their operands
- source operands can be *values* or *names of other reservation station entries* or *load buffer entries* that will produce the value
  - both operands don't have to be available at the same time
  - when both operand values have been computed, an instruction can be dispatched to its functional unit

## Reservation Stations

RAW hazards eliminated by **forwarding**

- source operand values that are computed after the registers are read are known by the functional unit or load buffer that will produce them
- results are immediately forwarded to functional units on the common data bus
- don't have to wait until for value to be written into the register file

Eliminate WAR & WAW hazards by **register renaming**

- name-dependent instructions refer to reservation station or load buffer locations for their sources, not the registers (as above)
- the last writer to the register updates it
- more reservation stations than registers, so eliminates more name dependences than a compiler can & exploit more parallelism
- examples on next slide

# Reservation Stations

Register renaming eliminates WAR & WAW hazards

- **Tag** in the reservation station/register file/store buffer indicates where the result will come from

## Handling WAR hazards

ld **F1**, \_

register **F1**'s tag *originally* specifies the entry in the load buffer for the **ld**

addf \_, **F1**, \_

**addf**'s reservation station entry specifies the **ld**'s entry in the load buffer for source operand 1

subf **F1**, \_

register **F1**'s tag *now* specifies the reservation station that holds **ld**

Does not matter if **ld** finishes after **subf**; **F1** will no longer claim it & **addf** will use its tag

## Reservation Stations

### Handling WAW hazards

addf **F1**, F0, F8      **F1**'s tag *originally* specifies **addf**'s entry in the reservation station

...

subf **F1**, F8, F14      **F1**'s tag *now* specifies **subf**'s entry in the reservation station

no register will claim the **addf** result if it completes last

# Tomasulo's Algorithm: More Key Features

## Common data bus (CDB)

- connects functional units & load buffer to reservations stations, registers, store buffer
- ships results to *all* hardware that could want an updated value
- eliminates RAW hazards: not have to wait until registers are written before consuming a value

## Distributed hazard detection & execution control

- each reservation station decides when to dispatch instructions to the function units
- each hardware data structure entry that needs values grabs the values itself: **snooping**
  - reservation stations, store buffer entries & registers have a tag saying where their data should come from
  - when it matches the data producer's tag on the bus, reservation stations, store buffer entries & registers grab the data

## Tomasulo's Algorithm: More Key Features

### Dynamic memory disambiguation

- **the issue:** don't want loads to bypass stores to the same location
- **the solution:**
  - loads associatively check addresses in store buffer
  - if an address match, grab the value

# Tomasulo's Algorithm: Execution Steps

## **Tomasulo functions**

(assume the instruction has been fetched)

- **issue & read**
  - structural hazard detection for reservation stations & load/store buffers
    - issue if no hazard
    - stall if hazard
  - read registers for source operands
    - put into reservation stations if values are in them
    - put tag of producing functional unit or load buffer if not  
(renaming the registers to eliminate WAR & WAW hazards)

## Tomasulo's Algorithm: Execution Steps

- **execute**
  - RAW hazard detection
  - snoop on common data bus for missing operands
  - dispatch instruction to a functional unit when obtain both operand values
  - execute the operation
  - calculate effective address & start memory operation
- **write**
  - broadcast result & reservation station id (tag) on the common data bus
  - reservation stations, registers & store buffer entries obtain the value through snooping

# Tomasulo's Algorithm: State

**Tomasulo state:** the information that the hardware needs to control distributed execution

- **operation** of the issued instructions waiting for execution (Op)
  - located in reservation stations
- **tags** that indicate the producer for a source operand (Q)
  - located in reservation stations, registers, store buffer entries
  - what unit (reservation station or load buffer) will produce the operand
  - special value (blank for us) if value already there
- **operand values** in reservation stations & load/store buffers (V)
- reservation station & load/store buffer **busy fields** (Busy)
- **addresses** in load/store buffers (for memory disambiguation)

# Example in the Book: 1

## Instruction Status Table

Instruction	Issue	Execute	Write Result	Which Cycle
ld F6, 34(R2)	yes	yes	yes	<b>first load has executed</b>
ld F2, 45(R3)	yes	yes		
multd F0, F2, F4	yes			
subd F8, F6, F2	yes			
divd F10, F0, F6	yes			
addd F6, F8, F2	yes			

## Reservation Stations

Name	Busy	Op	V <sub>j</sub>	V <sub>k</sub>	Q <sub>j</sub>	Q <sub>k</sub>
Add1	yes	subd	(Load1)			Load2
Add2	yes	addd			Add1	Load2
Add3	no					
Mult1	yes	multd		(F4)	Load2	
Mult2	yes	divd		(Load1)	Mult1	

## Register Status (Q<sub>i</sub>)

F0	F2	F4	F6	F8	F10	F12...
Mult1	Load2		Add2	Add1	Mult2	

## Example in the Book: 2

**Instruction Status Table**

Instruction	Issue	Execute	Write Result	Which Cycle
ld F6, 34(R2)	yes	yes	yes	<b>second load has executed</b>
ld F2, 45(R3)	yes	yes	yes	
multd F0, F2, F4	yes	yes		
subd F8, F6, F2	yes	yes		
divd F10, F0, F6	yes			
addd F6, F8, F2	yes			

**Reservation Stations**

Name	Busy	Op	V <sub>j</sub>	V <sub>k</sub>	Q <sub>j</sub>	Q <sub>k</sub>
Add1	yes	subd	(Load1)	(Load2)

## Register Status (Q<sub>i</sub>)

F0	F2	F4	F6	F8	F10	F12...
0	0		0	0	Mult2	

# Tomasulo's Algorithm

## Dynamic loop unrolling

- addf and st in each iteration has a different tag for the F0 value
- only the last iteration writes to F0
- effectively completely unrolling the loop

```
LOOP: ld F0, 0(R1)
      addf F0, F0, F1
      st F0, 0(R1)
      sub R1, R1, #8
      bnez R1, LOOP
```

# Tomasulo's Algorithm

## Dynamic loop unrolling

Nice features relative to static loop unrolling

- effectively increases number of registers (# reservations stations, load buffer entries, registers) but without register pressure
- dynamic memory disambiguation to prevent loads after stores with the same address from getting old data if they execute first
- simpler compiler

Downside

- loop control instructions still executed
- much more complex hardware

# Dynamic Scheduling

## Advantages over static scheduling

- more places to hold register values
- makes dispatch decisions dynamically, based on when instructions actually complete & operands are available
- can *completely* disambiguate memory references

## Effects of these advantages

- ⇒ more effective at exploiting parallelism (especially given compiler technology at the time)
  - increased instruction throughput
  - increased functional unit utilization
- ⇒ efficient execution of code compiled for a different pipeline
- ⇒ simpler compiler in theory

**Use both!**
