Inference in Bayesian networks

Chapter 14.4-5

Inference by enumeration

Slightly intelligent way to sum out variables from the joint without actually constructing its explicit representation

Simple query on the burglary network:

 $\mathbf{P}(B|j,m)$ $= \mathbf{P}(B, j, m)/P(j, m)$ $= \alpha \mathbf{P}(B, j, m)$ $= \alpha \stackrel{\sim}{\Sigma_e} \stackrel{\sim}{\Sigma_a} \mathbf{P}(B, e, a, j, m)$

Rewrite full joint entries using product of CPT entries:

 $= \alpha \sum_{e} \sum_{a} \mathbf{P}(B)P(e)\mathbf{P}(a|B,e)P(j|a)P(m|a)$ $= \alpha \mathbf{P}(B) \sum_{e} P(e) \sum_{a} \mathbf{P}(a|B,e) P(j|a) P(m|a)$

Recursive depth-first enumeration: O(n) space, $O(d^n)$ time

Chapter 14.4–5 1 Chapter 14.4-5 4

Outline

- ♦ Exact inference by enumeration
- ♦ Exact inference by variable elimination
- ♦ Approximate inference by stochastic simulation
- ♦ Approximate inference by Markov chain Monte Carlo

Chapter 14.4-5 2

Enumeration algorithm

```
function Enumeration-Ask(X, e, bn) returns a distribution over X
   inputs: X, the query variable
              \mathbf{e}, observed values for variables \mathbf{E}
              \mathit{bn}, a Bayesian network with variables \{X\}\,\cup\,\mathbf{E}\,\cup\,\mathbf{Y}
   \mathbf{Q}(X) \leftarrow a distribution over X, initially empty
   for each value x_i of X do
         extend {\bf e} with value x_i for X
         \mathbf{Q}(x_i) \leftarrow \text{Enumerate-All(Vars[bn], e)}
   return Normalize(Q(X))
```

function ENUMERATE-ALL(vars, e) returns a real number if Empty?(vars) then return 1.0

 $Y \leftarrow \text{First(}vars\text{)}$ $\mathbf{if}\ Y \ \mathsf{has}\ \mathsf{value}\ y \ \mathsf{in}\ \mathbf{e}$

then return $P(y \mid Pa(Y)) \times \text{Enumerate-All(Rest(vars), e)}$ else return Σ_y $P(y \mid Pa(Y)) \times \text{Enumerate-All(Rest(vars), } \mathbf{e}_y)$

where e_y is e extended with Y = y

Chapter 14.4-5 5

Inference tasks

```
Simple queries: compute posterior marginal \mathbf{P}(X_i|\mathbf{E}=\mathbf{e})
    \textbf{e.g.,}\ P(NoGas|Gauge = empty, Lights = on, Starts = false)
```

Conjunctive queries: $P(X_i, X_i | E = e) = P(X_i | E = e)P(X_i | X_i, E = e)$

Optimal decisions: decision networks include utility information; probabilistic inference required for P(outcome|action, evidence)

Value of information: which evidence to seek next?

Sensitivity analysis: which probability values are most critical?

Explanation: why do I need a new starter motor?

P(b).001 P(e) $P(\neg e)$.002 .998 P(a|b,e) $P(\neg a|b,e)$ $P(a|b, \neg e)$ $P(\neg a|b, \neg e)$ P(j|a) $P(j| \neg a)$ P(j|a) $P(j| \neg a)$ $P(m| \neg a)$ P(mla P(m)

Evaluation tree

Enumeration is inefficient: repeated computation e.g., computes P(j|a)P(m|a) for each value of e

Chapter 14.4-5 3 Chapter 14.4-5 6

Inference by variable elimination

Variable elimination: carry out summations right-to-left, storing intermediate results (factors) to avoid recomputation

$$\begin{split} \mathbf{P}(B|j,m) &= \alpha \underbrace{\mathbf{P}(B)}_{\tilde{B}} \underbrace{\sum_{e} \underbrace{P(e)}_{\tilde{E}} \sum_{a} \underbrace{\mathbf{P}(a|B,e)}_{\tilde{A}} \underbrace{P(j|a)}_{\tilde{M}} \underbrace{P(m|a)}_{\tilde{M}} \\ &= \alpha \mathbf{P}(B) \underbrace{\sum_{e} P(e)}_{\tilde{E}} \underbrace{\sum_{a} \mathbf{P}(a|B,e)}_{\tilde{P}(j|a)} f_{M}(a) \\ &= \alpha \mathbf{P}(B) \underbrace{\sum_{e} P(e)}_{\tilde{E}} \underbrace{\sum_{a} \mathbf{P}(a|B,e)}_{\tilde{f}_{J}(a)} f_{M}(a) \\ &= \alpha \mathbf{P}(B) \underbrace{\sum_{e} P(e)}_{\tilde{E}} \underbrace{F_{AJM}(b,e)}_{\tilde{f}_{JM}} f_{M}(a) \\ &= \alpha \mathbf{P}(B) \underbrace{\sum_{e} P(e)}_{\tilde{f}_{AJM}} f_{M}(b,e) \text{ (sum out } A) \\ &= \alpha \mathbf{P}(B) \underbrace{f_{\tilde{E}}}_{\tilde{E}JM}(b) \text{ (sum out } E) \\ &= \alpha f_{B}(b) \times \underbrace{f_{\tilde{E}}}_{\tilde{E}JM}(b) \end{split}$$

Irrelevant variables

Consider the query P(JohnCalls|Burglary = true)

$$P(J|b) = \alpha P(b) \mathop{\Sigma} P(e) \mathop{\Sigma} P(a|b,e) P(J|a) \mathop{\Sigma} P(m|a)$$

Sum over m is identically 1; M is **irrelevant** to the query

Thm 1: Y is irrelevant unless $Y \in Ancestors(\{X\} \cup \mathbf{E})$

Here, X = JohnCalls, $\mathbf{E} = \{Burglary\}$, and $Ancestors(\{X\} \cup \mathbf{E}) = \{Alarm, Earthquake\}$ so MaryCalls is irrelevant

(Compare this to backward chaining from the query in Horn clause KBs)

Chapter 14.4-5 10

Variable elimination: Basic operations

Chapter 14.4–5 7

Chapter 14.4-5 8

Summing out a variable from a product of factors: move any constant factors outside the summation add up submatrices in pointwise product of remaining factors

$$\sum_{x} f_1 \times \cdots \times f_k = f_1 \times \cdots \times f_i \sum_{x} f_{i+1} \times \cdots \times f_k = f_1 \times \cdots \times f_i \times f_{\bar{X}}$$

assuming f_1,\ldots,f_i do not depend on X

Pointwise product of factors f_1 and f_2 :

$$\begin{split} f_1(x_1,\dots,x_j,y_1,\dots,y_k) &\times f_2(y_1,\dots,y_k,z_1,\dots,z_l) \\ &= f(x_1,\dots,x_j,y_1,\dots,y_k,z_1,\dots,z_l) \\ \text{E.g., } f_1(a,b) &\times f_2(b,c) = f(a,b,c) \end{split}$$

Irrelevant variables contd.

Defn: moral graph of Bayes net: marry all parents and drop arrows

Defn: ${\bf A}$ is <u>m-separated</u> from ${\bf B}$ by ${\bf C}$ iff separated by ${\bf C}$ in the moral graph

Thm 2: Y is irrelevant if m-separated from X by ${\bf E}$

For P(JohnCalls|Alarm=true), both Burglary and Earthquake are irrelevant

Chapter 14.4-5 11

Variable elimination algorithm

 $\begin{aligned} & \textbf{function ELIMINATION-ASK}(X, \mathbf{e}, bn) \ \textbf{returns a distribution over} \ X \\ & \textbf{inputs:} \ X, \ \textbf{the query variable} \\ & \textbf{e}, \ \textbf{evidence specified as an event} \\ & bn, \ \textbf{a belief network specifying joint distribution} \ \mathbf{P}(X_1, \dots, X_n) \\ & factors \leftarrow []; \ vars \leftarrow \text{Reverse}(\text{Vars}[bn]) \\ & \textbf{for each} \ var \ \textbf{in} \ vars \ \textbf{do} \\ & factors \leftarrow [\text{Make-Factor}(var, \mathbf{e})|factors| \\ & \textbf{if} \ var \ \textbf{is} \ \textbf{a} \ \textbf{hidden} \ \textbf{variable then} \ factors \leftarrow \text{Sum-Out}(var, factors) \\ & \textbf{return} \ \text{Normalize}(\text{Pointwise-Product}(factors)) \end{aligned}$

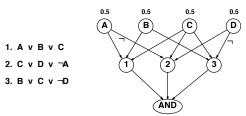

Complexity of exact inference

Singly connected networks (or polytrees):

- any two nodes are connected by at most one (undirected) path
- time and space cost of variable elimination are $O(d^k n)$

Multiply connected networks:

- can reduce 3SAT to exact inference \Rightarrow NP-hard
- equivalent to counting 3SAT models ⇒ #P-complete

Chapter 14.4-5 9 Chapter 14.4-5 12

Inference by stochastic simulation

Basic idea:

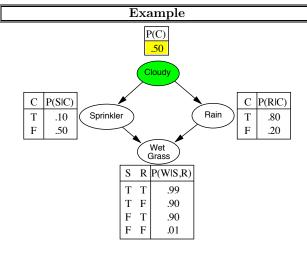

- 1) Draw N samples from a sampling distribution S
- 2) Compute an approximate posterior probability \hat{P}
- 3) Show this converges to the true probability $\stackrel{?}{P}$

0.5

Outline:

return x

- Sampling from an empty network
- Rejection sampling: reject samples disagreeing with evidence
- Likelihood weighting: use evidence to weight samples
- Markov chain Monte Carlo (MCMC): sample from a stochastic process whose stationary distribution is the true posterior

Chapter 14.4-5 13 Chapter 14.4-5 16

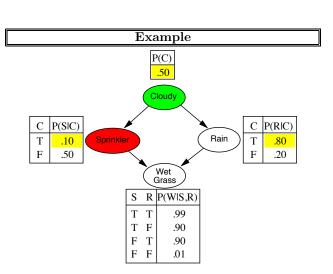

Sampling from an empty network

 $\begin{aligned} & \textbf{function Prior-Sample}(bn) \ \ \textbf{returns} \ \ \textbf{an event sampled from} \ \ bn \\ & \textbf{inputs:} \ \ bn, \ \textbf{a} \ \textbf{belief network specifying joint distribution} \ \mathbf{P}(X_1,\dots,X_n) \\ & \textbf{x} \leftarrow \textbf{an event with} \ n \ \ \textbf{elements} \\ & \textbf{for} \ \ i = 1 \ \textbf{to} \ n \ \ \textbf{do} \\ & x_i \leftarrow \textbf{a} \ \ \textbf{random sample from} \ \mathbf{P}(X_i \mid parents(X_i)) \\ & \text{given the values of} \ Parents(X_i) \ \ \textbf{in} \ \ \textbf{x} \end{aligned}$

Example P(C) .50 Cloudy C P(SIC) P(RIC) Rain Sprinkler T .10 T .80 F .50 F .20 Wet Grass $R \mid P(W|S,R)$ T T .99 .90 T F F T .90 F F .01

Chapter 14.4-5 14 Chapter 14.4-5 17

Example P(C) .50 Cloudy P(SIC) C P(RIC) Sprinkler Rain T .10 T .80 F .50 F .20 Wet Grass $R \mid P(W|S,R)$ Т T .99 .90 T F F T .90 F .01

Chapter 14.4–5 19

Sampling from an empty network contd.

Probability that PRIORSAMPLE generates a particular event $S_{PS}(x_1\dots x_n)=\prod_{i=1}^n P(x_i|parents(X_i))=P(x_1\dots x_n)$ i.e., the true prior probability

E.g., $S_{PS}(t, f, t, t) = 0.5 \times 0.9 \times 0.8 \times 0.9 = 0.324 = P(t, f, t, t)$

Let $N_{PS}(x_1 \dots x_n)$ be the number of samples generated for event x_1, \dots, x_n

Then we have

$$\lim_{N \to \infty} \hat{P}(x_1, \dots, x_n) = \lim_{N \to \infty} N_{PS}(x_1, \dots, x_n)/N$$

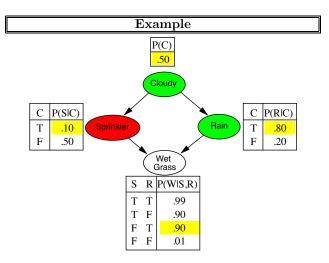

$$= S_{PS}(x_1, \dots, x_n)$$

$$= P(x_1 \dots x_n)$$

That is, estimates derived from PRIORSAMPLE are consistent

Shorthand: $\hat{P}(x_1, \ldots, x_n) \approx P(x_1 \ldots x_n)$

Chapter 14.4-5 22

Chapter 14.4-5 20

Rejection sampling

 $\hat{\mathbf{P}}(X|\mathbf{e})$ estimated from samples agreeing with \mathbf{e}

 $\begin{aligned} & \textbf{function Rejection-Sampling}(X, \mathbf{e}, bn, N) \ \textbf{returns} \ \textbf{an estimate} \ \textbf{of} \ P(X|\mathbf{e}) \\ & \textbf{local variables:} \ \textbf{N}, \ \textbf{a} \ \textbf{vector} \ \textbf{of} \ \textbf{counts} \ \textbf{over} \ X, \ \textbf{initially zero} \\ & \textbf{for} \ j = 1 \ \textbf{to} \ N \ \textbf{do} \\ & \textbf{x} \leftarrow \text{PRIOR-Sample}(bn) \\ & \textbf{if} \ \textbf{x} \ \textbf{is} \ \textbf{consistent} \ \textbf{with} \ \textbf{e} \ \textbf{then} \\ & \textbf{N}[x] \leftarrow \textbf{N}[x] + 1 \ \textbf{where} \ x \ \textbf{is} \ \textbf{the} \ \textbf{value} \ \textbf{of} \ X \ \textbf{in} \ \textbf{x} \\ & \textbf{return} \ \textbf{NORMALIZE}(\textbf{N}[X]) \end{aligned}$

E.g., estimate P(Rain|Sprinkler = true) using 100 samples 27 samples have Sprinkler = true Of these, 8 have Rain = true and 19 have Rain = false.

 $\hat{\mathbf{P}}(Rain|Sprinkler = true) = \text{Normalize}(\langle 8, 19 \rangle) = \langle 0.296, 0.704 \rangle$

Similar to a basic real-world empirical estimation procedure

Chapter 14.4–5 23

Example P(C) .50 Cloudy C P(SIC) C P(RIC) Sprinkler Rain T .10 T .80 F .50 F .20 R P(WIS,R) T T .99 T F .90 F Τ .90 F .01

Analysis of rejection sampling

$$\begin{split} \hat{\mathbf{P}}(X|\mathbf{e}) &= \alpha \mathbf{N}_{PS}(X,\mathbf{e}) \\ &= \mathbf{N}_{PS}(X,\mathbf{e})/N_{PS}(\mathbf{e}) & \text{(normalized by } N_{PS}(\mathbf{e})\text{)} \\ &\approx \mathbf{P}(X,\mathbf{e})/P(\mathbf{e}) & \text{(property of PRIORSAMPLE)} \\ &= \mathbf{P}(X|\mathbf{e}) & \text{(defn. of conditional probability)} \end{split}$$

Hence rejection sampling returns consistent posterior estimates

Problem: hopelessly expensive if $P(\mathbf{e})$ is small

 $P(\mathbf{e})$ drops off exponentially with number of evidence variables!

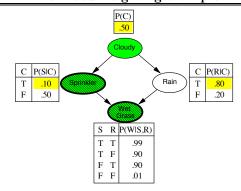

Chapter 14.4-5 21 Chapter 14.4-5 24

Likelihood weighting

Idea: fix evidence variables, sample only nonevidence variables, and weight each sample by the likelihood it accords the evidence

```
\begin{aligned} & \textbf{function Likelihood-Weighting}(X, \mathbf{e}, bn, N) \ \textbf{returns} \ \textbf{an estimate} \ \textbf{of} \ P(X | \mathbf{e}) \\ & \textbf{local variables:} \ \textbf{W}, \ \textbf{a} \ \textbf{vector} \ \textbf{of} \ \textbf{weighted} \ \textbf{counts} \ \textbf{over} \ X_i \ \textbf{initially zero} \\ & \textbf{for} \ j = 1 \ \textbf{to} \ N \ \textbf{do} \\ & \textbf{x}, w \leftarrow \textbf{Weighted-Sample}(bn) \\ & \textbf{W}[x] \leftarrow \textbf{W}[x] + w \ \textbf{where} \ x \ \textbf{is} \ \textbf{the} \ \textbf{value} \ \textbf{of} \ X \ \textbf{in} \ \textbf{x} \\ & \textbf{return Normalize}(\textbf{W}[X]) \\ & \hline & \textbf{function Weighted-Sample}(bn, \textbf{e}) \ \textbf{returns} \ \textbf{an event} \ \textbf{and} \ \textbf{a} \ \textbf{weight} \\ & \textbf{x} \leftarrow \textbf{an event} \ \textbf{with} \ n \ \textbf{elements}; \ w \leftarrow 1 \\ & \textbf{for} \ i = 1 \ \textbf{to} \ n \ \textbf{do} \\ & \textbf{if} \ X_i \ \textbf{has} \ \textbf{a} \ \textbf{value} \ x_i \ \textbf{in} \ \textbf{e} \\ & \textbf{then} \ w \leftarrow w \times P(X_i = x_i \mid parents(X_i)) \\ & \textbf{else} \ x_i \leftarrow \textbf{a} \ \textbf{random sample} \ \textbf{from} \ \textbf{P}(X_i \mid parents(X_i)) \\ & \textbf{return} \ \textbf{x}, \ w \end{aligned}
```

Likelihood weighting example

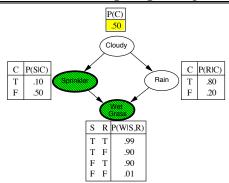

w = 1.0

Chapter 14.4-5 25

Chapter 14.4-5 28

Likelihood weighting example

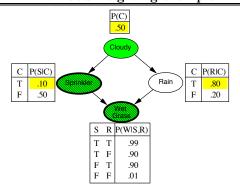

w = 1.0

Chapter 14.4-5 26

 $w=1.0\times0.1$

Likelihood weighting example

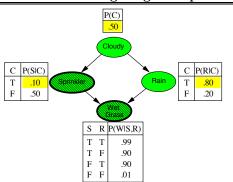

Chapter 14.4-5 29

Likelihood weighting example

w=1.0

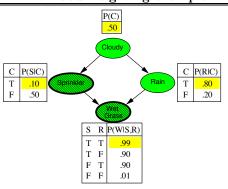

Likelihood weighting example

 $w=1.0\times0.1$

Chapter 14.4-5 27 Chapter 14.4-5 27

Likelihood weighting example

 $w = 1.0 \times 0.1$

Chapter 14.4-5 31

Approximate inference using MCMC

"State" of network = current assignment to all variables.

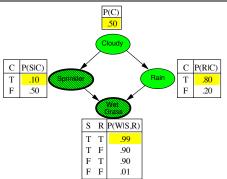

Generate next state by sampling one variable given Markov blanket Sample each variable in turn, keeping evidence fixed

```
\begin{aligned} & \textbf{function MCMC-Ask}(X, \mathbf{e}, bn, N) \textbf{ returns} \textbf{ an estimate of } P(X|\mathbf{e}) \\ & \textbf{ local variables: } \mathbf{N}[X], \textbf{ a vector of counts over } X, \textbf{ initially zero} \\ & Z, \textbf{ the nonevidence variables in } bn \\ & \mathbf{x}, \textbf{ the current state of the network, initially copied from } \mathbf{e} \\ & \textbf{ initialize } \mathbf{x} \textbf{ with random values for the variables in } \mathbf{Y} \\ & \textbf{ for } j = 1 \textbf{ to } N \textbf{ do} \\ & \textbf{ for each } Z_i \textbf{ in } \mathbf{Z} \textbf{ do} \\ & \textbf{ sample the value of } Z_i \textbf{ in } \mathbf{x} \textbf{ from } \mathbf{P}(Z_i|mb(Z_i)) \\ & \textbf{ given the values of } MB(Z_i) \textbf{ in } \mathbf{x} \\ & \mathbf{N}[x] \leftarrow \mathbf{N}[x] + 1 \textbf{ where } x \textbf{ is the value of } X \textbf{ in } \mathbf{x} \\ & \textbf{ return } \textbf{ NORMALIZE}(\mathbf{N}[X]) \end{aligned}
```

Can also choose a variable to sample at random each time

Chapter 14.4-5 34

Likelihood weighting example

 $w = 1.0 \times 0.1 \times 0.99 = 0.099$

Chapter 14.4–5 32

The Markov chain

With Sprinkler = true, WetGrass = true, there are four states:

Wander about for a while, average what you see

Chapter 14.4-5 35

Likelihood weighting analysis

Sampling probability for $\operatorname{WeightedSample}$ is

$$S_{WS}(\mathbf{z}, \mathbf{e}) = \prod_{i=1}^{l} P(z_i | parents(Z_i))$$

Note: pays attention to evidence in **ancestors** only

⇒ somewhere "in between" prior and
posterior distribution

Weight for a given sample \mathbf{z}, \mathbf{e} is $w(\mathbf{z}, \mathbf{e}) = \prod_{i=1}^{m} P(e_i|parents(E_i))$

Weighted sampling probability is

 $S_{WS}(\mathbf{z}, \mathbf{e})w(\mathbf{z}, \mathbf{e})$

 $= \prod_{i=1}^{l} P(z_i|parents(Z_i)) \quad \prod_{i=1}^{m} P(e_i|parents(E_i))$

 $= P(\mathbf{z}, \mathbf{e})$ (by standard global semantics of network)

Hence likelihood weighting returns consistent estimates but performance still degrades with many evidence variables because a few samples have nearly all the total weight

MCMC example contd.

 $\textbf{Estimate } \mathbf{P}(Rain|Sprinkler = true, WetGrass = true)$

Sample Cloudy or Rain given its Markov blanket, repeat. Count number of times Rain is true and false in the samples.

E.g., visit 100 states

31 have Rain = true, 69 have Rain = false

 $\hat{\mathbf{P}}(Rain|Sprinkler = true, WetGrass = true) \\ = \text{Normalize}(\langle 31, 69 \rangle) = \langle 0.31, 0.69 \rangle$

Theorem: chain approaches stationary distribution: long-run fraction of time spent in each state is exactly proportional to its posterior probability

Chapter 14.4-5 33 Chapter 14.4-5 34

Markov blanket sampling

 $\label{eq:market} \begin{aligned} & \mathsf{Markov} \; \mathsf{blanket} \; \mathsf{of} \; Cloudy \; \mathsf{is} \\ & Sprinkler \; \mathsf{and} \; Rain \\ & \mathsf{Markov} \; \mathsf{blanket} \; \mathsf{of} \; Rain \; \mathsf{is} \\ & Cloudy, \; Sprinkler, \; \mathsf{and} \; WetGrass \end{aligned}$

Probability given the Markov blanket is calculated as follows:

 $P(x_i'|mb(X_i)) = P(x_i'|parents(X_i)) \prod_{Z_j \in Children(X_i)} P(z_j|parents(Z_j))$

Easily implemented in message-passing parallel systems, brains

Main computational problems:

- 1) Difficult to tell if convergence has been achieved
- 2) Can be wasteful if Markov blanket is large: $P(X_i|mb(X_i)) \ \ \text{won't change much (law of large numbers)}$

Chapter 14.4-5 37

Summary

Exact inference by variable elimination:

- polytime on polytrees, NP-hard on general graphs
- space = time, very sensitive to topology

Approximate inference by LW, MCMC:

- $-\ LW$ does poorly when there is lots of (downstream) evidence
- LW, MCMC generally insensitive to topology
- Convergence can be very slow with probabilities close to $1\ \mbox{or}\ 0$
- Can handle arbitrary combinations of discrete and continuous variables

Chapter 14.4-5 38
