G-1

Agenda

- Parser Semantic Actions
- Intermediate Representations
 - Abstract Syntax Trees (ASTs)
 - Linear Representations
 - & more

G-3

What's a Parser to Do?

- Idea: at significant points in the parse perform a *semantic action*
 - Typically when a production is reduced (LR) or at a convenient point in the parse (LL)
- Typical semantic actions
 - Build (and return) a representation of the parsed chunk of the input (compiler)
 - Perform some sort of computation and return result (interpreter)

G-4

Intermediate Representations

- In most compilers, the parser builds an *intermediate representation* of the program
- Rest of the compiler transforms the IR for efficiency and eventually translates it to final code
 - Often will transform initial IR to one or more different IRs along the way

G-5

IR Design

- Decisions affect speed and efficiency of the rest of the compiler
- Desirable properties
 - Easy to generate
 - Easy to manipulate
 - Expressive
 - Appropriate level of abstraction
- Different tradeoffs depending on compiler goals
- Different tradeoffs in different parts of the same compiler

G-6

Types of IRs

- Three major categories
 - Structural
 - Linear
 - Hybrid
- Some basic examples now; more when we get to later phases of the compiler

G-7

Levels of Abstraction

- Key design decision: how much detail to expose
 - Affects possibility and profitability of various optimizations
 - Structural IRs are typically fairly high-level
 - Linear IRs are typically low-level
 - But these generalizations aren't always true

G-8

Example: Array Reference

A[i,j]

```
loadl 1 => r1
sub rj,r1 => r2
loadl 10 => r3
mult r2,r3 => r4
sub ri,r1 => r5
add r4,r5 => r6
loadl @A => r7
add r7,r6 => r8
load r8 => r9
```

G-9

Structural IRs

- Typically reflect source (or other higher-level) language structure
- Tend to be large
- Examples: syntax trees, DAGs
- Particularly useful for source-to-source transformations

10/18/2005

G-10

Concrete Syntax Trees

- The full grammar is needed to guide the parser, but contains many extraneous details
 - Chain productions
 - Rules that control precedence and associativity
- Typically the full syntax tree does not need to be used explicitly

10/18/2005

© 2002-05 Hal Perkins & UW CSE

G-11

Syntax Tree Example

- Concrete syntax for $x=2*(n+m);$

10/18/2005

© 2002-05 Hal Perkins & UW CSE

G-12

Abstract Syntax Trees

- Want only essential structural information
 - Omit extraneous junk
- Can be represented explicitly as a tree or in a linear form
 - Example: LISP/Scheme S-expressions are essentially ASTs

10/18/2005

© 2002-05 Hal Perkins & UW CSE

G-13

AST Example

- AST for $x=2*(n+m)$;

10/18/2005

G-14

Linear IRs

- Pseudo-code for an abstract machine
- Level of abstraction varies
- Simple, compact data structures
- Examples: stack machine code, three-address code

10/18/2005

© 2002-05 Hal Perkins & UW CSE

G-15

Stack Machine Code

- Originally used for stack-based computers (famous example: B5000)
- Now used for Java (.class files), C# (MSIL)
- Advantages
 - Compact; mostly 0-address opcodes
 - Easy to generate
 - Simple to translate to naive machine code
 - But need to do better in production compilers

10/18/2005

© 2002-05 Hal Perkins & UW CSE

G-16

Stack Code Example

- Hypothetical code for $x=2*(n+m)$;
pushaddr x
pushconst 2
pushval n
pushval m
add
mult
store

10/18/2005

© 2002-05 Hal Perkins & UW CSE

G-17

Three-Address code

- Many different representations
- General form: $x \leftarrow y \text{ (op) } z$
 - One operator
 - Maximum of three names
- Example: $x=2*(n+m)$; becomes
t1 $\leftarrow n + m$
t2 $\leftarrow 2 * t1$
x $\leftarrow t2$

10/18/2005

© 2002-05 Hal Perkins & UW CSE

G-18

Three Address Code (cont)

- Advantages
 - Resembles code for actual machines
 - Explicitly names intermediate results
 - Compact
 - Often easy to rearrange
- Various representations
 - Quadruples, triples, SSA
 - Much more later...

10/18/2005

© 2002-05 Hal Perkins & UW CSE

G-19

Hybrid IRs

- Combination of structural and linear
- Level of abstraction varies
- Example: control-flow graph

10/18/2005

© 2002-05 Hal Perkins & UW CSE

G-20

What to Use?

- Common choice: all(!)
 - AST or other structural representation built by parser and used in early stages of the compiler
 - Closer to source code
 - Good for semantic analysis
 - Facilitates some higher-level optimizations
 - Flatten to linear IR for later stages of compiler
 - Closer to machine code
 - Exposes machine-related optimizations
 - Hybrid forms in optimization phases

10/18/2005

© 2002-05 Hal Perkins & UW CSE

G-21

Coming Attractions

- Representing ASTs
- Working with ASTs
 - Where do the algorithms go?
 - Is it really object-oriented?
 - Visitor pattern
- Then: semantic analysis, type checking, and symbol tables
