CSEP 527 Spring 2016

5 – Motifs: Representation & Discovery

Outline

Previously: Learning from data

MLE: Max Likelihood Estimators

EM: Expectation Maximization (MLE w/hidden data)

These Slides:

Bio: Expression & regulation

Expression: creation of gene products

Regulation: when/where/how much of each gene product; complex and critical

Comp: using MLE/EM to find regulatory motifs in biological sequence data

Gene Expression & Regulation

Gene Expression

Recall a gene is a DNA sequence for a protein To say a gene is expressed means that it

- is transcribed from DNA to RNA
- the mRNA is processed in various ways
- is exported from the nucleus (eukaryotes)
- is translated into protein

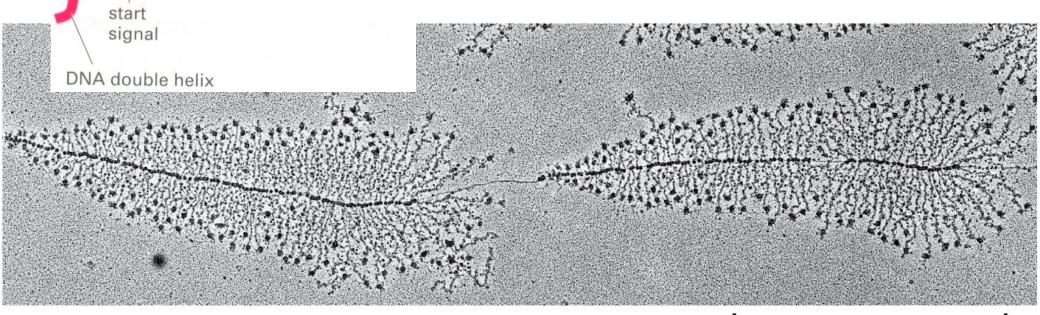

A key point: not all genes are expressed all the time, in all cells, or at equal levels

attached RNA transcript direction of polymerase movement and RNA chain growth RNA polymerase start signal DNA double helix

RNA Transcription

Some genes heavily transcribed (many are not)

1 μm

Regulation

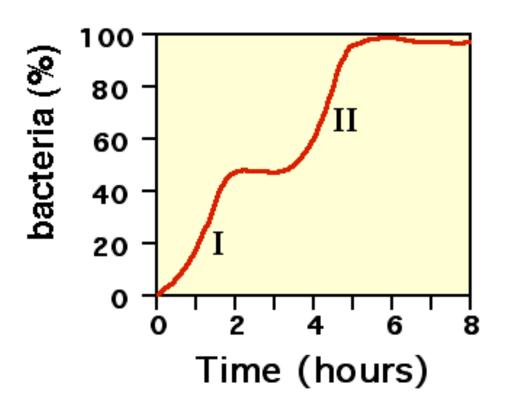

In most cells, pro- or eukaryote, easily a 10,000-fold difference between least- and most-highly expressed genes

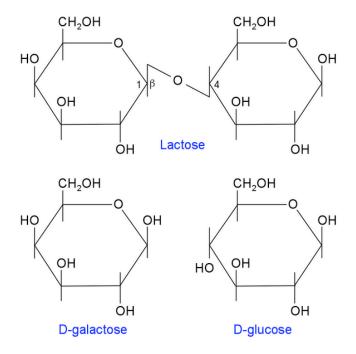

Regulation happens at all steps. E.g., some genes are highly transcribed, some are not transcribed at all, some transcripts can be sequestered then released, or rapidly degraded, some are weakly translated, some are very actively translated, ...

All are important, but below, focus on 1st step only:

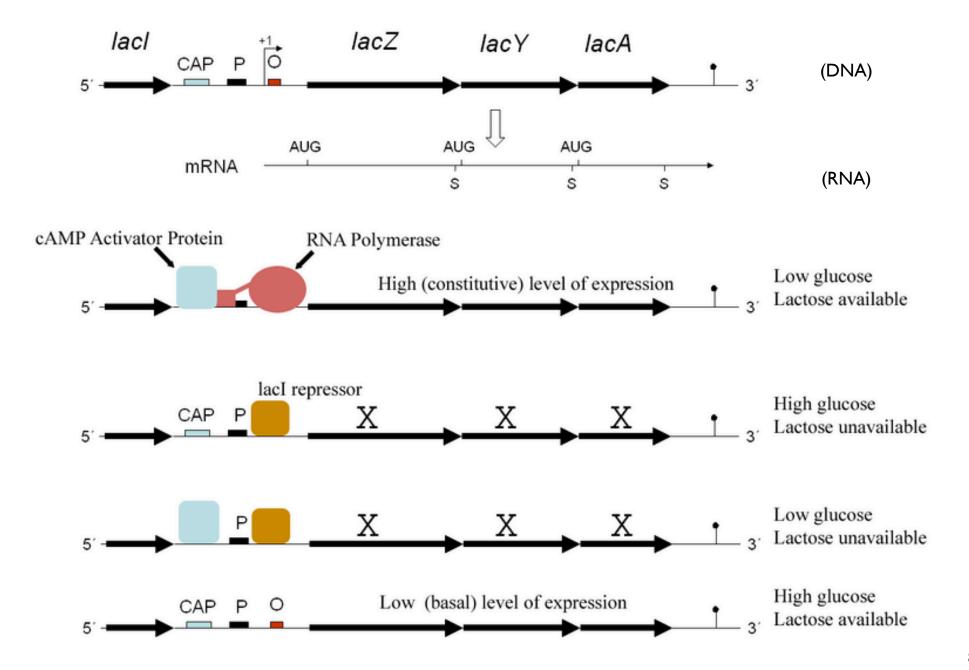

transcriptional regulation

DNA Binding Proteins

A variety of DNA binding proteins (so-called "transcription factors"; a significant fraction, perhaps 5-10%, of all human proteins) modulate transcription of protein coding genes

The Double Helix

In the groove

Different patterns of potential H bonds at edges of different base pairs, accessible esp. in major groove

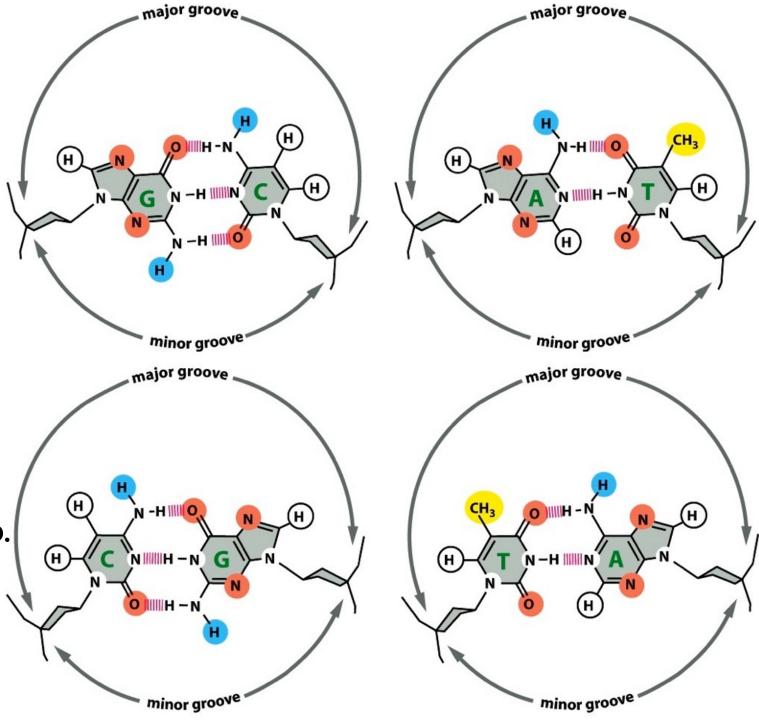

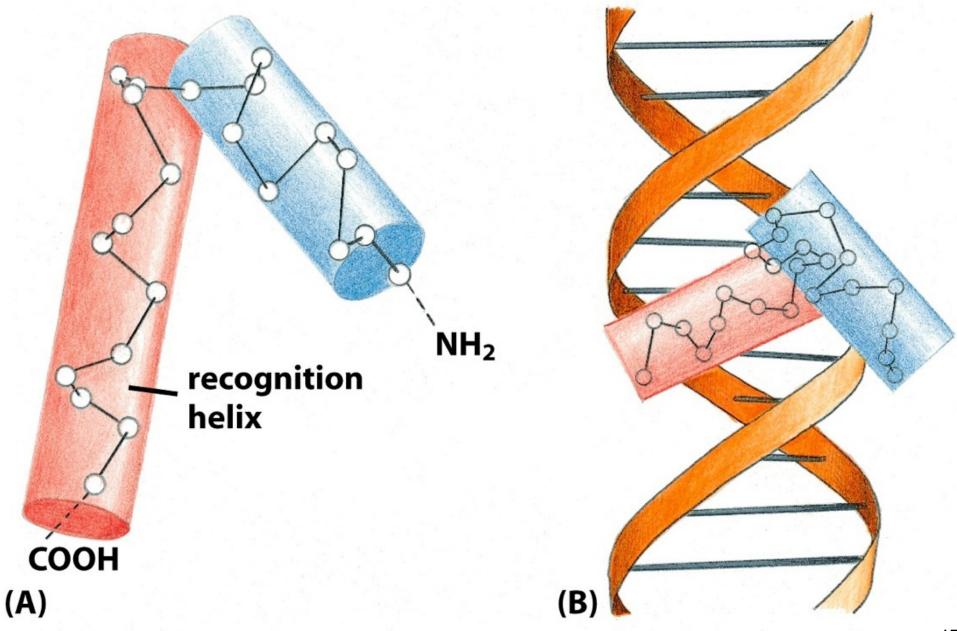

Figure 7-7 Molecular Biology of the Cell 5/e (© Garland Science 2008)

Helix-Turn-Helix DNA Binding Motif

H-T-H Dimers

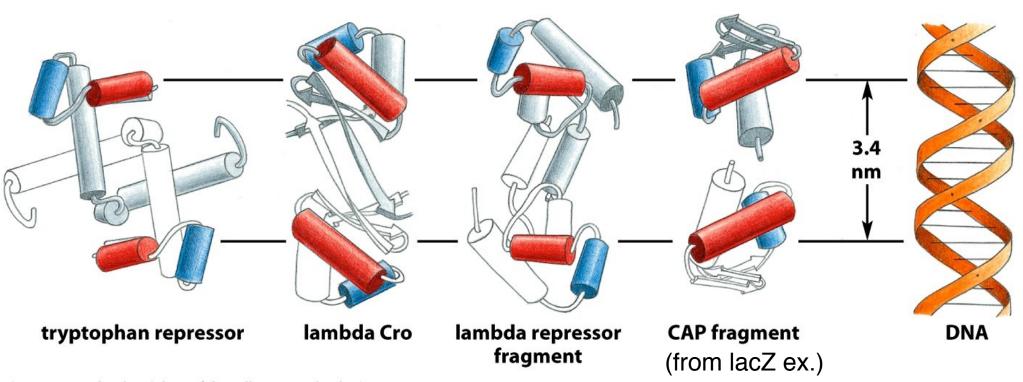

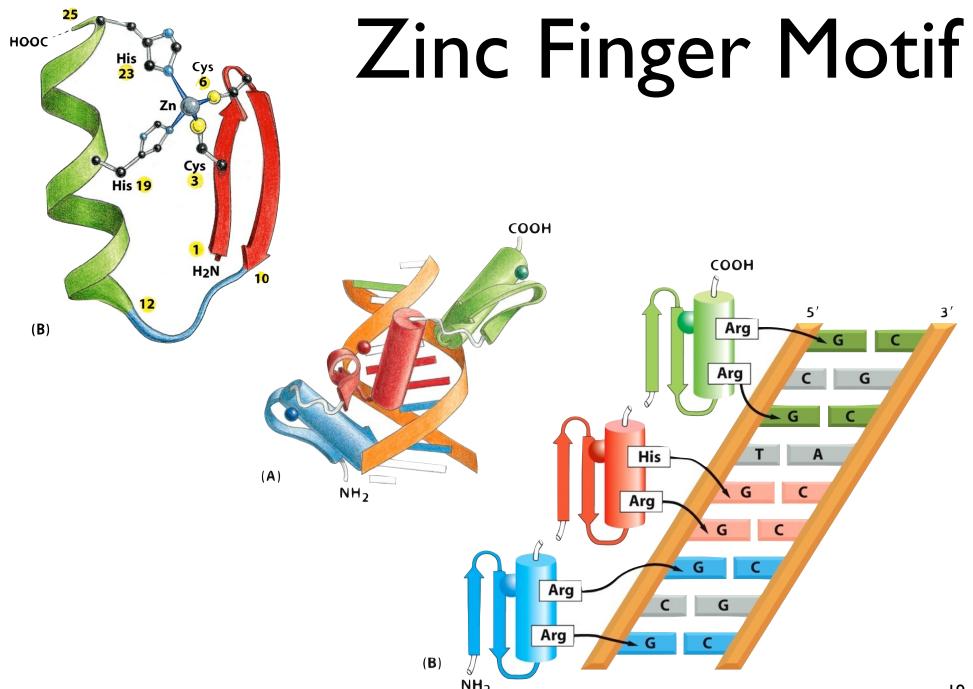

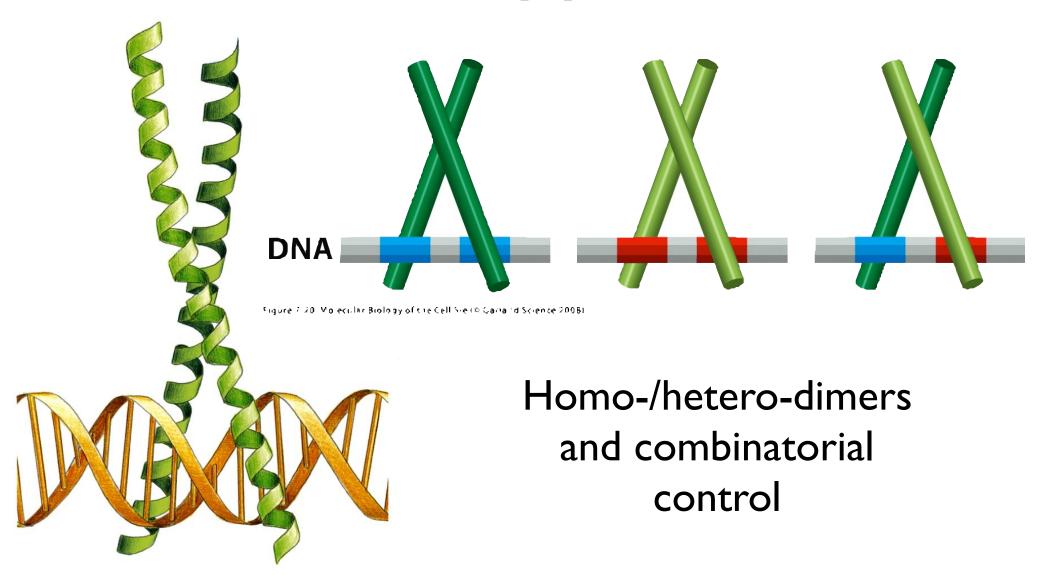

Figure 7-11 Molecular Biology of the Cell 5/e (© Garland Science 2008)

Bind 2 DNA patches, ~ I turn apart Increases both specificity and affinity

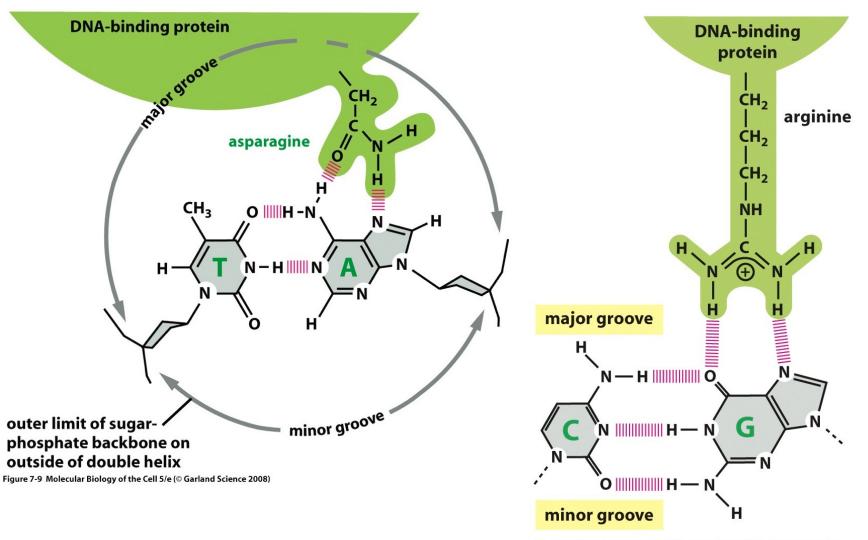

Leucine Zipper Motif

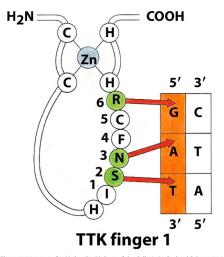

http://www.rcsb.org/pdb/explore/jmol.do?structureId=IMDY&bionumber=I

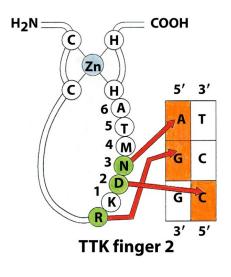

We understand some Protein/DNA interactions

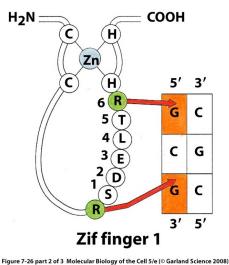

22

But the overall DNA binding "code" still defies prediction

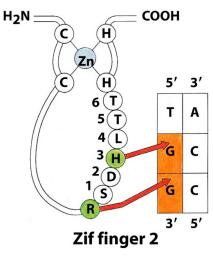

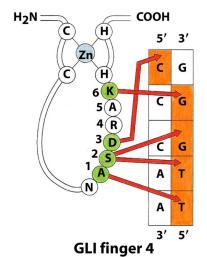

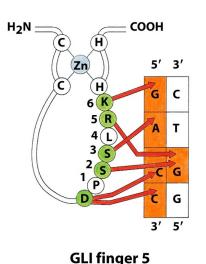

Figure 7-26 part 1 of 3 Molecular Biology of the Cell 5/e (© Garland Science 2008)

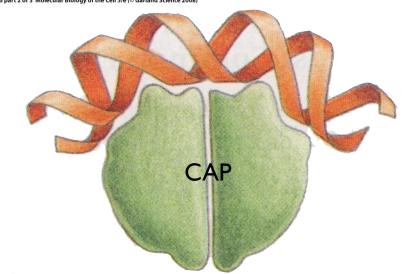

Figure 7-26 part 3 of 3 Molecular Biology of the Cell 5/e (© Garland Science 2008)

Summary

Proteins can "bind" DNA to regulate gene expression (i.e., production of proteins, including themselves)

This is widespread

Complex, combinatorial control is both possible and commonplace

Sequence Motifs

Sequence Motifs

Motif: "a recurring salient thematic element"

Last few slides described structural motifs in proteins

Equally interesting are the sequence motifs in DNA to which these proteins bind - e.g., one leucine zipper dimer might bind (with varying affinities) to dozens or hundreds of similar sequences

DNA binding site summary

Complex "code"

Short patches (4-8 bp)

Often near each other (I turn = 10 bp)

Often reverse-complements (dimer symmetry)

Not perfect matches

E. coli Promoters

"TATA Box" ~ 10bp upstream of

transcription start TACGAT

How to define it?

TAAAAT

Consensus is TATAAT TATACT

BUT all differ from it GATAAT

Allow k mismatches? TATGAT

Equally weighted? TATGTT

Wildcards like R,Y? ({A,G}, {C,T}, resp.)

E. coli Promoters

- "TATA Box" consensus TATAAT
- ~10bp upstream of transcription start Not exact: of 168 studied (mid 80's)
 - nearly all had 2/3 of TAxyzT
 - 80-90% had all 3
 - 50% agreed in each of x,y,z
 - no perfect match
- Other common features at -35, etc.

TATA Box Frequencies

pos	1	2	3	4	5	6
Α	2	95	26	59	51	1
С	9	2	14	13	20	3
G	10	1	16	15	13	0
T	79	3	44	13	17	96

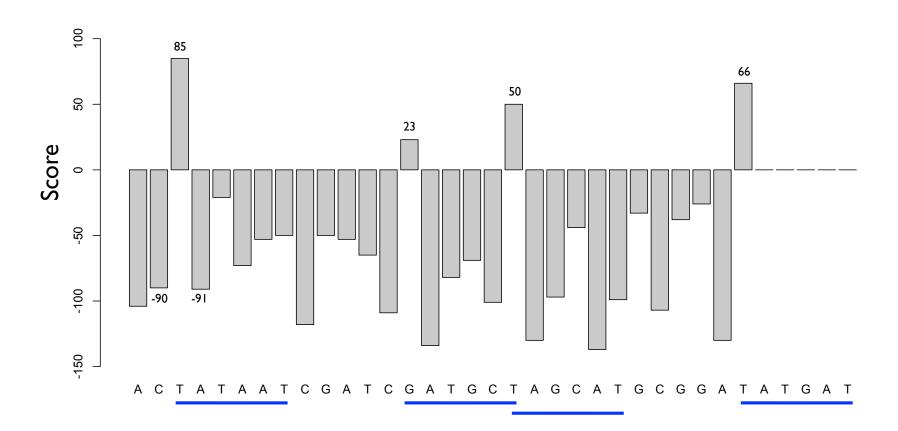

TATA Scores

A "Weight Matrix Model" or "WMM"

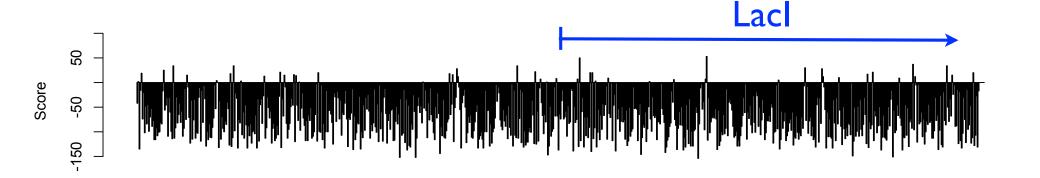

pos	1	2	3	4	5	6
Α	-36	19	1	12	10	-46
С	-15	-36	-8	-9	-3	-31
G	-13	-46	-6	-7	-9	-46(?)
T	17	-31	8	-9	-6	19

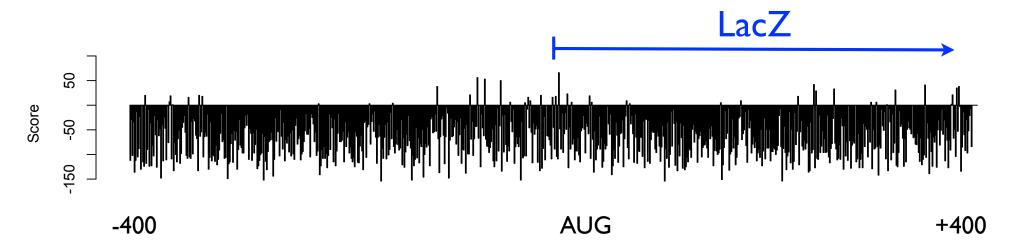

Scanning for TATA

Scanning for TATA

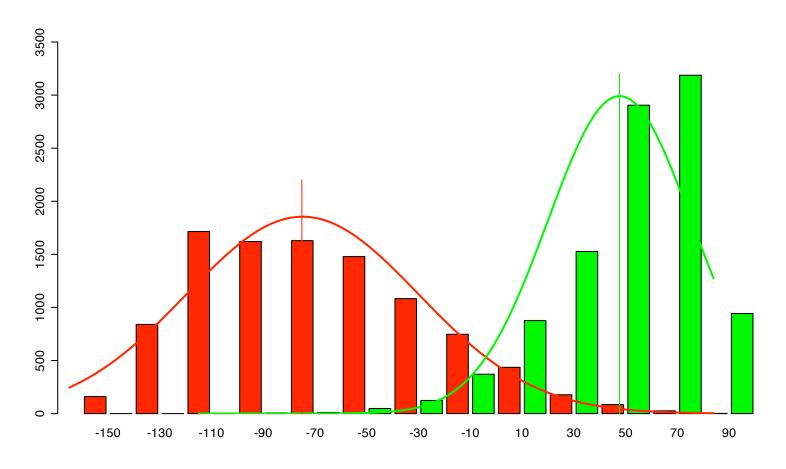

TATA Scan at 2 genes

Score Distribution

(Simulated)

10⁴ random 6-mers from foreground (green) or uniform background (red)₃₅

Weight Matrices: Statistics

Assume:

 $f_{b,i}$ = frequency of base b in position i in TATA

 f_b = frequency of base b in all sequences

Log likelihood ratio, given $S = B_1 B_2 ... B_6$:

$$\log \left(\frac{P(S|\, \text{``tata''})}{P(S|\, \text{``non-tata''})} \right) = \log \frac{\prod_{i=1}^6 f_{B_i,i}}{\prod_{i=1}^6 f_{B_i}} = \sum_{i=1}^6 \log \frac{f_{B_i,i}}{f_{B_i}}$$

Assumes independence

Neyman-Pearson

Given a sample $x_1, x_2, ..., x_n$, from a distribution $f(...|\Theta)$ with parameter Θ , want to test hypothesis $\Theta = \theta_1$ vs $\Theta = \theta_2$.

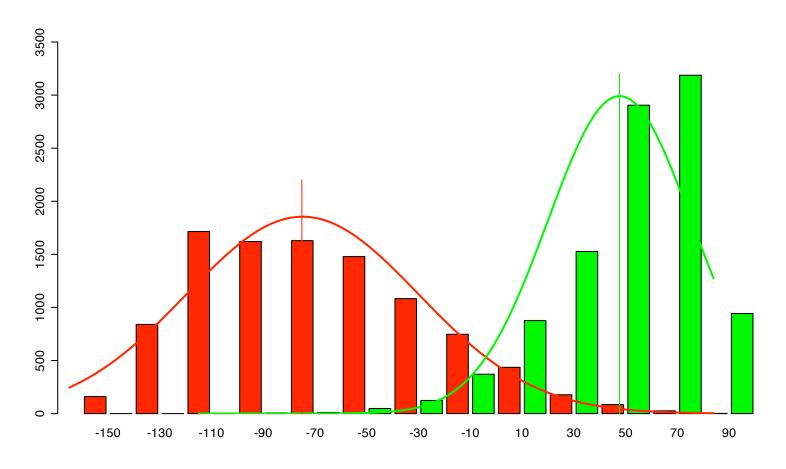

Might as well look at likelihood ratio:

$$\frac{f(x_1, x_2, ..., x_n | \theta_1)}{f(x_1, x_2, ..., x_n | \theta_2)} > \tau$$

(or log likelihood ratio)

Score Distribution

(Simulated)

10⁴ random 6-mers from foreground (green) or uniform background (red)₃₈

What's best WMM?

Given, say, 168 sequences $s_1, s_2, ..., s_k$ of length 6, assumed to be generated at random according to a WMM defined by 6 x (4-1) unknown parameters θ , what's the best θ ?

E.g., what's MLE for θ given data $s_1, s_2, ..., s_k$?

Answer: like coin flips or dice rolls, count frequencies per position. (Possible HW?)

Weight Matrices: Biophysics

Experiments show ~80% correlation of log likelihood weight matrix scores to measured binding energies [Fields & Stormo, 1994]

Another WMM example

8 Sequences:

ATG

ATG

ATG

ATG

ATG

GTG

GTG

TTG

Freq.	Col I	Col 2	Col 3		
Α	0.625	0	0		
С	0	0	0		
G	0.25	0			
Т	0.125		0		

LLR	Col I	Col 2	Col 3
Α	1.32	-8	-8
С	-8	-8	-8
G	0		2
Т	-	2	-8

Log-Likelihood Ratio:

$$\log_2 \frac{f_{x_i,i}}{f_{x_i}}, \ f_{x_i} = \frac{1}{4}$$
 (uniform background)

Non-uniform Background

- E. coli DNA approximately 25% A, C, G, T
- *M. jannaschi* 68% A-T, 32% G-C

LLR from previous example, assuming

$$f_A = f_T = 3/8$$

 $f_C = f_G = 1/8$

LLR	Col I	Col 2	Col 3
Α	0.74	8	8
С	-8	8	-8
G		8	3
T	-1.58	1.42	-8

e.g., G in col 3 is 8 x more likely via WMM than background, so (\log_2) score = 3 (bits).

Relative Entropy

AKA Kullback-Liebler Divergence, AKA Information Content

Intuitively "distance", but technically not, since it's asymmetric

Given distributions P, Q

$$H(P||Q) = \sum_{x \in \Omega} P(x) \log \frac{P(x)}{Q(x)} \ge \mathbf{0}$$

Notes:

Let
$$P(x) \log \frac{P(x)}{Q(x)} = 0$$
 if $P(x) = 0$ [since $\lim_{y \to 0} y \log y = 0$]

Undefined if
$$0 = Q(x) < P(x)$$

WMM: How "Informative"? Mean score of site vs bkg?

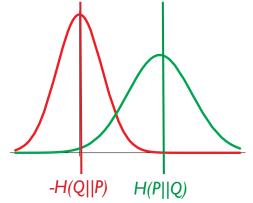

For any fixed length sequence x, let

P(x) = Prob. of x according to WMM

Q(x) = Prob. of x according to background

Relative Entropy:

$$H(P||Q) = \sum_{x \in \Omega} P(x) \log_2 \frac{P(x)}{Q(x)}$$

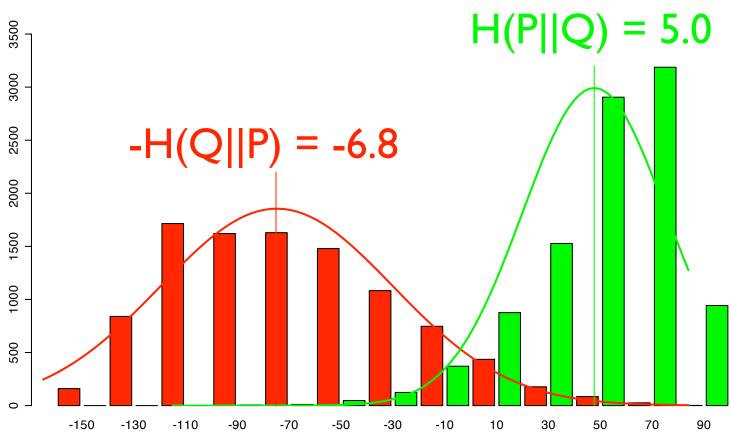

H(P||Q) is expected log likelihood score of a sequence randomly chosen from WMM (wrt background);

-H(Q||P) is expected score of Background (wrt WMM)

Expected score difference: H(P||Q) + H(Q||P)

WMM Scores vs Relative Entropy

On average, foreground model scores > background by 11.8 bits (score difference of 118 on 10x scale used in examples above).

For a WMM:

$$H(P||Q) = \sum_{i} H(P_i||Q_i)$$

where P_i and Q_i are the WMM/background distributions for column i.

Proof: exercise

Hint: Use the assumption of independence between WMM columns

WMM Example, cont.

Freq.	Col I	Col 2	Col 3		
Α	0.625	0	0		
С	0	0	0		
G	0.25	0	Ī		
Т	0.125	I	0		

Uniform

LLR	Col I	Col 2	Col 3	
Α	1.32	8	8	
С	8	8	8	
G	0	-8	2	
Т	-	2	8	
RelEnt	0.7	2	2	4.

Non-uniform

LLR	Col I	Col 2	Col 3	
Α	0.74	-∞	-8	
С	-8	-∞	-8	
G		-∞	3	
Т	-1.58	1.42	8	
RelEnt	0.51	1.42	3	4.93
			·	47

Pseudocounts

Are the $-\infty$'s a problem?

Certain that a given residue *never* occurs in a given position? Then $-\infty$ just right.

Else, it may be a small-sample artifact

Typical fix: add a pseudocount to each observed count—small constant (e.g., .5, I)

Sounds ad hoc; there is a Bayesian justification

WMM Summary

- Weight Matrix Model (aka Position Weight Matrix, PWM, Position Specific Scoring Matrix, PSSM, "possum", 0th order Markov model)
- Simple statistical model assuming independence between adjacent positions
- To build: count (+ pseudocount) letter frequency per position, log likelihood ratio to background
- To scan: add LLRs per position, compare to threshold
- Generalizations to higher order models (i.e., letter frequency per position, conditional on neighbor) also possible, with enough training data (kth order MM)

How-to Questions

Given aligned motif instances, build model?

Frequency counts (above, maybe w/ pseudocounts)

Given a model, find (probable) instances

Scanning, as above

Given unaligned strings thought to contain a motif, find it? (e.g., upstream regions of co-

Hard ... rest of lecture.

expressed genes)

Motif Discovery

Motif Discovery

Based on the above, a natural approach to motif discovery, given, say, unaligned upstream sequences of genes thought to be co-regulated, is to find a set of subsequences of *max relative* entropy

cgatcTACGATaca...
tagTAAAATtttc...
ccgaTATACTcc...
ggGATAATgagg...
gactTATGATaa...
ccTATGTTtgcc...

Unfortunately, this is NP-hard [Akutsu]

Motif Discovery: 4 example approaches

Brute Force

Greedy search

Expectation Maximization

Gibbs sampler

Brute Force

Input:

Motif length L, plus sequences s_1 , s_2 , ..., s_k (all of length n+L-1, say), each with one instance of an unknown motif

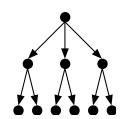

Algorithm:

Build all k-tuples of length L subsequences, one from each of $s_1, s_2, ..., s_k$ (n^k such tuples)

Compute relative entropy of each

Pick best

Brute Force, II

Input:

Motif length L, plus seqs s_1 , s_2 , ..., s_k (all of length n+L-1, say), each with one instance of an unknown motif

Algorithm in more detail:

Build singletons: each len L subseq of each s_1 , s_2 , ..., s_k (nk sets)

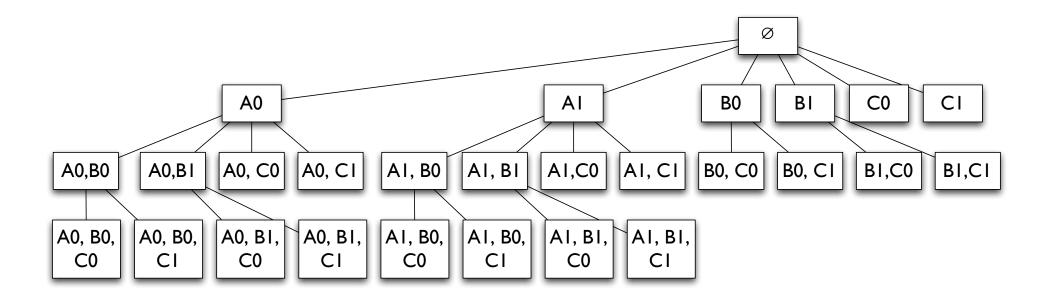

Extend to pairs: len L subseqs of each pair of seqs $(n^2\binom{k}{2})$ sets)

Then triples: len L subseqs of each triple of seqs $(n^3\binom{k}{3})$ sets)

Repeat until all have k sequences $(n^k \binom{k}{k})$ sets)

(n+1)k in total; compute relative entropy of each; pick best

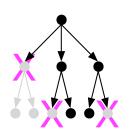

Example

Three sequences (A, B, C), each with two possible motif positions (0,1)

Greedy Best-First

[Hertz, Hartzell & Stormo, 1989, 1990]

Input:

Sequences $s_1, s_2, ..., s_k$; motif length L;

"breadth" d, say d = 1000

Algorithm:

As in brute, but discard all but best d relative entropies at each stage

Expectation Maximization [MEME, Bailey & Elkan, 1995]

Input (as above):

Sequences s_1 , s_2 , ..., s_k ; motif length l; background model; again assume one instance per sequence (variants possible)

Algorithm: EM

Visible data: the sequences

Hidden data: where's the motif

$$Y_{i,j} = \begin{cases} 1 & \text{if motif in sequence } i \text{ begins at position } j \\ 0 & \text{otherwise} \end{cases}$$

Parameters θ : The WMM

MEME Outline

Typical EM algorithm:

Parameters $\theta^{(t)}$ at t^{th} iteration, used to estimate where the motif instances are (the hidden variables)

Use those estimates to re-estimate the parameters θ to maximize likelihood of observed data, giving $\theta^{(t+1)}$ Repeat

Key: given a few good matches to best motif, expect to pick more

Cartoon Example

xATAyz

CATGACTAG CATAAT CCGAT

TATAAT TTCCCAGGGATAGCA

TACAATAGGACCA TAGAAT GCGC

Expectation Step

(where are the motif instances?)

$$\widehat{Y}_{i,j} = E(Y_{i,j} \mid s_i, \theta^t) \xrightarrow{\mathbb{E}^{\{0, P^{(0)} + 1, P^{(1)}\}}} \mathbb{E}^{\{0, P^{(0)} + 1, P^{(1)}\}}$$

$$= P(Y_{i,j} = 1 \mid s_i, \theta^t) \xrightarrow{P(Y_{i,j} = 1 \mid \theta^t)} \mathbb{E}^{\{0, P^{(0)} + 1, P^{(1)}\}}$$

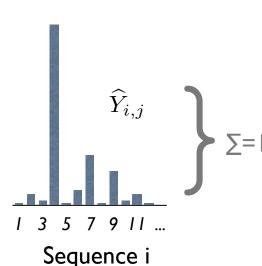

$$= P(S_i \mid Y_{i,j} = 1, \theta^t) \xrightarrow{P(Y_{i,j} = 1 \mid \theta^t)} \mathbb{E}^{\{0, P^{(0)} + 1, P^{(1)}\}}$$

$$= CP(S_i \mid Y_{i,j} = 1, \theta^t)$$

$$= CP(S_i \mid Y_{i,j} = 1, \theta^t)$$

$$= CP(S_i \mid Y_{i,j} = 1, \theta^t)$$

where c' is chosen so that $\sum_{i} \hat{Y}_{i,j} = 1$.

Recall slide 33

Maximization Step

(what is the motif?)

Find θ maximizing expected log likelihood:

$$\begin{split} Q(\theta \mid \theta^t) &= E_{Y \sim \theta^t} [\log P(s, Y \mid \theta)] \\ &= E_{Y \sim \theta^t} [\log \prod_{i=1}^k P(s_i, Y_i \mid \theta)] \\ &= E_{Y \sim \theta^t} [\sum_{i=1}^k \log P(s_i, Y_i \mid \theta)] \\ &= E_{Y \sim \theta^t} [\sum_{i=1}^k \sum_{j=1}^{|s_i| - l + 1} Y_{i,j} \log P(s_i, Y_{i,j} = 1 \mid \theta)] \\ &= E_{Y \sim \theta^t} [\sum_{i=1}^k \sum_{j=1}^{|s_i| - l + 1} Y_{i,j} \log(P(s_i \mid Y_{i,j} = 1, \theta) P(Y_{i,j} = 1 \mid \theta))] \\ &= \sum_{i=1}^k \sum_{j=1}^{|s_i| - l + 1} E_{Y \sim \theta^t} [Y_{i,j}] \log P(s_i \mid Y_{i,j} = 1, \theta) + C \\ &= \sum_{i=1}^k \sum_{j=1}^{|s_i| - l + 1} \widehat{Y}_{i,j} \log P(s_i \mid Y_{i,j} = 1, \theta) + C \end{split}$$

M-Step (cont.)

$$Q(\theta \mid \theta^t) = \sum_{i=1}^k \sum_{j=1}^{|s_i|-l+1} \widehat{Y}_{i,j} \log P(s_i \mid Y_{i,j} = 1, \theta) + C$$

Exercise: Show this is maximized by "counting" letter frequencies over all possible motif instances, with counts weighted by $\widehat{Y}_{i,j}$, again the "obvious" thing.

Initialization

- 1. Try every motif-length substring, and use as initial θ a WMM with, say, 80% of weight on that sequence, rest uniform
- 2. Run a few iterations of each
- 3. Run best few to convergence

(Having a supercomputer helps):

http://meme.sdsc.edu/

Josiah Williard Gibbs, 1839-1903, American physicist, a pioneer of thermodynamics

How to Average

An old problem:

n random variables:

Joint distribution (p.d.f.):

Some function:

Want Expected Value:

$$x_1, x_2, \dots, x_k$$
 $P(x_1, x_2, \dots, x_k)$
 $f(x_1, x_2, \dots, x_k)$
 $E(f(x_1, x_2, \dots, x_k))$

How to Average

$$E(f(x_1, x_2, \dots, x_k)) = \int_{x_1} \int_{x_2} \dots \int_{x_k} f(x_1, x_2, \dots, x_k) \cdot P(x_1, x_2, \dots, x_k) dx_1 dx_2 \dots dx_k$$

Approach I: direct integration (rarely solvable analytically, esp. in high dim)

Approach 2: numerical integration (often difficult, e.g., unstable, esp. in high dim)

Approach 3: Monte Carlo integration

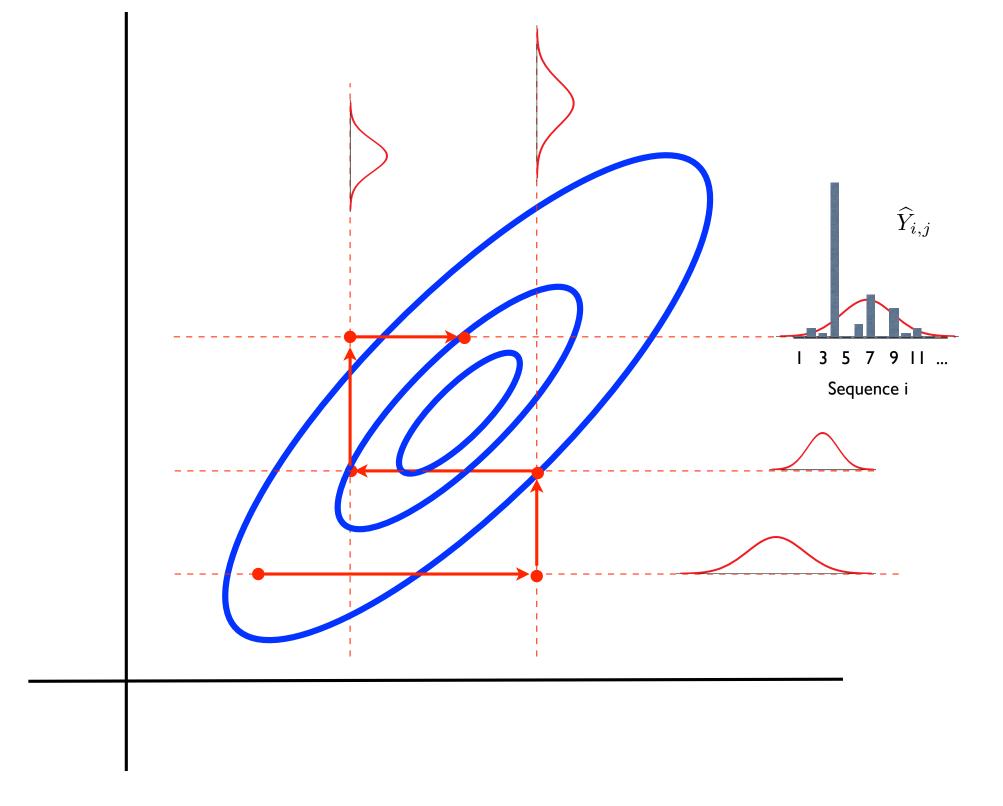

sample $\vec{x}^{(1)}, \vec{x}^{(2)}, \dots \vec{x}^{(n)} \sim P(\vec{x})$ and average:

$$E(f(\vec{x})) \approx \frac{1}{n} \sum_{i=1}^{n} f(\vec{x}^{(i)})$$

Markov Chain Monte Carlo (MCMC)

- Independent sampling also often hard, but not required for expectation
- MCMC $ec{X}_{t+1} \sim P(ec{X}_{t+1} \mid ec{X}_t)$ w/ stationary dist = P
- Simplest & most common: Gibbs Sampling $P(x_i \mid x_1, x_2, \dots, x_{i-1}, x_{i+1}, \dots, x_k)$
- Algorithm

for t = I to
$$\infty$$
 $t+1$ t for i = I to k do: $x_{t+1,i} \sim P(x_{t+1,i} \mid x_{t+1,1}, x_{t+1,2}, \dots, x_{t+1,i-1}, x_{t,i+1}, \dots, x_{t,k})$

Input: again assume sequences $s_1, s_2, ..., s_k$ with one length w motif per sequence

Motif model: WMM

Parameters: Where are the motifs?

for
$$1 \le i \le k$$
, have $1 \le x_i \le |s_i| - w + 1$

"Full conditional": to calc

$$P(x_i = j \mid x_1, x_2, \dots, x_{i-1}, x_{i+1}, \dots, x_k)$$

build WMM from motifs in all sequences except i, then calc prob that motif in i^{th} seq occurs at j by usual "scanning" alg.

Overall Gibbs Alg

Randomly initialize x_i 's

for
$$t = 1$$
 to ∞
for $i = 1$ to k
discard motif instance from s_i ;
recalc WMM from rest
for $j = 1 ... |s_i| - w + 1$

Similar to MEME, but it would average over, rather than

sample from

calculate prob that i^{th} motif is at j:

average over,
$$P(x_i = j \mid x_1, x_2, \dots, x_{i-1}, x_{i+1}, \dots, x_k)$$

pick new x_i according to that distribution

Issues

Burnin - how long must we run the chain to reach stationarity?

Mixing - how long a post-burnin sample must we take to get a good sample of the stationary distribution? In particular:

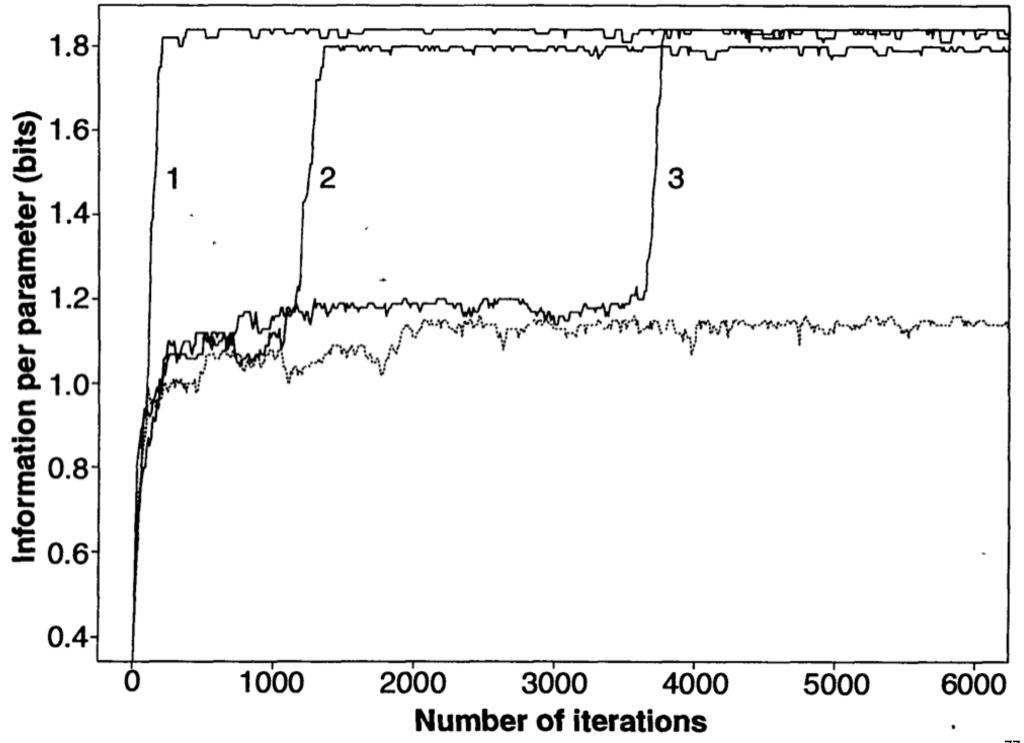

Samples are not independent; may not "move" freely through the sample space Many isolated modes

Variants & Extensions

"Phase Shift" - may settle on suboptimal solution that overlaps part of motif. Periodically try moving all motif instances a few spaces left or right.

Algorithmic adjustment of pattern width: Periodically add/remove flanking positions to maximize (roughly) average relative entropy per position

Multiple patterns per string

Assessing computational tools for the discovery of transcription factor binding sites

Methodology

13 tools

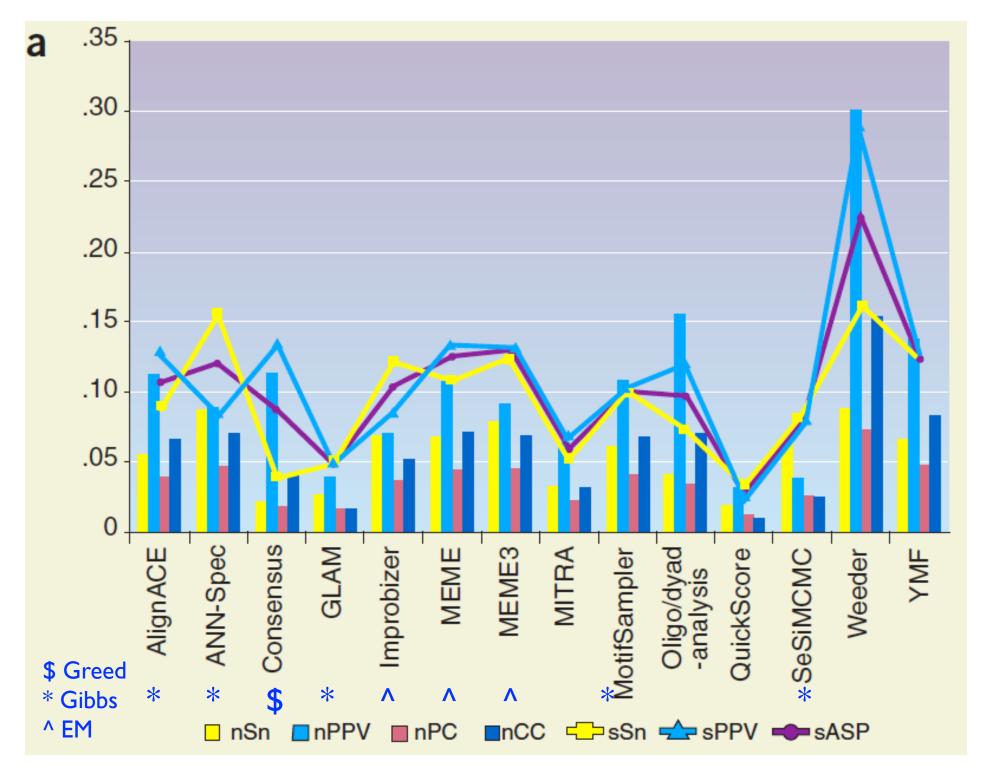

Real 'motifs' (Transfac)

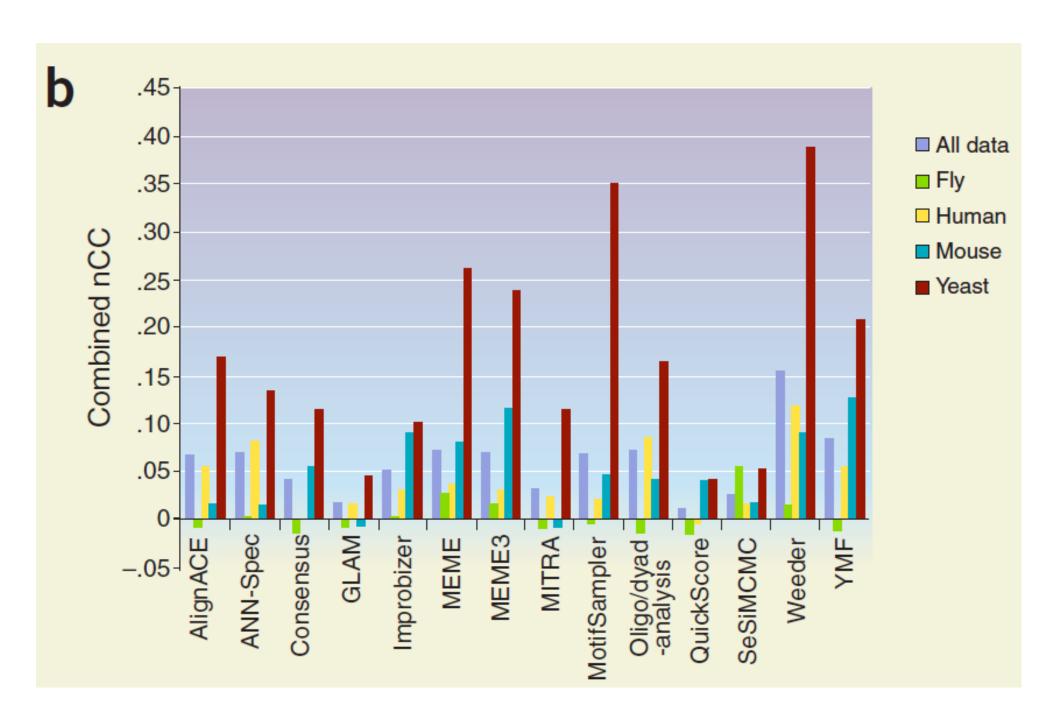

56 data sets (human, mouse, fly, yeast)

'Real', 'generic', 'Markov'

Expert users, top prediction only

"Blind" - sort of

Lessons

Evaluation is hard (esp. when "truth" is unknown)

Accuracy low

partly reflects limitations in evaluation methodology (e.g. ≤ I prediction per data set; results better in synth data)

partly reflects difficult task, limited knowledge (e.g. yeast > others)

No clear winner re methods or models

Motif Discovery Summary

Important problem: a key to understanding gene regulation

Hard problem: short, degenerate signals amidst much noise

Many variants have been tried, for representation, search, and discovery. We looked at only a few:

Weight matrix models for representation & search

Greedy, MEME and Gibbs for discovery

Still room for improvement. E.g., ChIP-seq and Comparative genomics (cross-species comparison) are very promising.
