

Exceptions with Speculative Instructions

Techniques to avoid exception handling on wrong-path instructions

- ignore until instruction is no longer speculative
- handle resumable exceptions & return undefined value for terminating exceptions
 - if wrong path, value ignored
 - if right path, program is incorrect & will generate incorrect results

Exceptions with Speculative Instructions

Techniques to avoid exception handling on wrong-path instructions

- handle a terminating exception only if the result is about to be used by nonspeculative instruction
 - **poison bit** on each register; **speculative bit** in each instruction
 - poison bit of result register set if speculative instruction results in terminating exception
 - a use of a poisoned result by a speculative instruction sets the poison bit for its result
 - a use by nonspeculative instruction triggers exception handling
 - buffer results of speculative instructions until commit

Exceptions with Speculative Instructions

Techniques to avoid exception handling on wrong-path instructions

- “check load address” instruction
- located where load used to be
- hardware tracks if store to this address
- if yes, reload
- might have to reexecute dependent instructions
