ACCEP'TORS FROM VAN WIJNGAARDEN GRAMMARS:
AN APPLICATION OF 'PROGRAMMING LANGUAGES FOR AUTOMATA'

Introduction

Baker (1970) has characterized the type 0 and type 1 languages in terms of van Wijngaarden grammars (vWg). It is the purpose of the present paper to make a formal presentation of a construction which is only outlined there. The construction is of a nondeterministic linear bounded automaton (lba)- or turing machine (tm)- acceptor for the language specified by a vWg.

The construction is presented here as a schema for a program in a language which is a modification of that defined by Knuth and Bigelow (1967). The programming language (for the classes of lba and tm) defined here may itself be of interest, partly in confirmation of the usefulness of the programming language technique in theory of computing, partly as an extension of the range of applicability of that technique, and partly for the additional language features it includes.

The section of the present paper titled 'background' is extracted from Baker (1970). It is reproduced here to provide a setting for the rest of the present paper, the principal purpose of which is to supply details of the construction in the proof of theorem 2.
Tm and lba are here specified as sets of quadruples \((p, a, b, q)\), where \(p\) and \(q\) are machine states, \(a\) is a tape symbol, and \(b\) is either a tape symbol or one of the symbols \(\{L, R\}\), which indicate one-square shifts of the tape scan point, left and right respectively. The quadruple \((p, a, b, q)\) occurs in the specification of a machine if and only if the machine, in state \(p\) and scanning \(a\) on its tape, may enter state \(q\) and (if \(b\) is a tape symbol) print \(b\) or (if \(b \in \{L, R\}\)) shift its tape scan according to \(b\).

These machines are nondeterministic (i.e. \((p, a) \mapsto (q, b)\) is not required to be univocal.), halt only for want of an instruction (i.e. only by reaching a state \(p\), scanning a symbol \(a\) for which no quadruple \((p, a, b, q)\) occurs in the specification), and accept an input by halting in one of a designated set of accepting states. Inputs to these machines are assumed to be left- and right- end-marked with '\(\ell'\) and '\(\$'\) respectively. Lba differ from tm only in that, if \((p, '\ell' \text{ [resp. $']}, b, q)\) occurs in the specification of an lba, then \(b \in \{R, '\ell'\} \text{ [resp. \{L, $'\}]}\). It is convenient here to suppose, in considering tm computations, that each tape square not considered as input contains '\(\$'\), i.e. to suppose that '\(\$'\) is the natural tape blank \([1]\).

---

1. In the main construction of the present paper, this supposition is only significant to the details of the operation of the procedure 'endtape'. The reader will have no difficulty in bringing the construction given here into conformity with any other reasonable convention concerning blank tape.
\ denotes set difference: \( A \setminus B = \{ x \in A \mid x \notin B \} \).

The notion string is not formally defined here, but is supposed to have the following properties: A string \( x \) has a unique length \( |x| > 0 \). A string of length one is distinct from its unique component. \( \emptyset \) is the empty string, the unique string of length zero.

If \( S \) is a set, then \( S^* \) is the set of strings whose components are elements of \( S \), and \( S^+ = S^* \setminus \{ \emptyset \} \).

If \( S \) is a set and \( n \) a natural number, then \( S^n \) is the \( n \)th cartesian power of \( S \), the set of ordered \( n \)-tuples of elements of \( S \). It is here explicitly not assumed that \( S^n = \{ x \in S^* \mid n = |x| \} \).

The vinculum (\( \bar{\quad} \)) is used here to indicate a string of length one. Thus: if \( x \) and \( y \) are strings, \( |\bar{xy}| = 1 \), \( |\bar{x}\bar{y}| = 2 \), \( |xy| = |x| + |y| \); also, \( \bar{s} \) is the string of length one whose component is the string of length one whose component is \( s \); also, \( \bar{\emptyset} \neq \emptyset \). This vinculum notation is used only when strings of strings are under consideration. Otherwise, a string of length one is notationally identified with its component.

Notations and definitions not otherwise specified follow Hopcroft and Ullman (1969). Invocation of 'familiar' results and techniques without specific reference may also be taken as referring to the same, in particular to chapters 6-9.
Definition 1: A van Wijngaarden grammar (vWG) is an ordered sextuple $(M, N, R_M, B, R, s)$, where:

- $M$ is a finite set, the **metavariabes**.
- $N$ is a finite set, the **protovariabes**, $M \cap N = \emptyset$.
- $R_M$ is a finite set of **metarules**, $X \rightarrow Y$, where $\{ X, Y \} \subseteq (M \cup N)^*$, with $V_{\text{WeM}}(M, N, R_M, W)$ a csg.
- $B$ is a finite set, the **basic strings**, $B \subseteq N^*$.
- $R$ is a finite set of **rules** $(f_0, f_1, \ldots, f_k, h)$ $(k \geq 0)$,
  where $\forall i = 0 \exists n_i \geq 0 f_i \in (N^*)^{n_i+1}$ and $h$ is a function,
  $\text{dom}(h) = \{ (i, j) \mid i \in \{0, 1, \ldots, k\} \text{ and } f_i \in (N^*)^{n_i+1}$
  and $j \in \{1, \ldots, n_i\}\}$, $\text{ran}(h) \subseteq M$.
- $s \in N^*$, $s$ is the **starting variable**.

In this paper, it is supposed that '$,$' is not a meta- or protovariable of any vWG.

To permit an explicit presentation of the notions to be defined here, the following example of a vWG with a finite language is given. (Also see figure 2.)

$$G_0 = (\{ T \},$$
$$\{ a, d, e, f, n, p, s, v, w \},$$
$$\{ T \rightarrow f, T \rightarrow p \},$$
$$\{ \bar{a}, \bar{n}, \bar{v}, \bar{w} \},$$
$$\{ (\bar{s}, \bar{n}, f_2, \bar{v}, f_4, \{ ((2, 1), T), ((4, 1), T) \}) \},$$
$$\{ (\bar{a}, \bar{v}, \emptyset), (\bar{p}_a, \emptyset), (\bar{f}_e, \emptyset), (\bar{p}_e, \bar{a}, \emptyset) \},$$
$$\bar{s} \},$$
where $f_2 = (\bigtriangleup, \bar{a})$ and $f_4 = (\bigtriangledown, \bar{e})$. 
(This example is suggested by a familiar analysis of a small piece of the English language, according to the following correspondence:

- tense auxiliary -ed ending future noun past sentence verb will

\[ T \quad a \quad d \quad e \quad f \quad n \quad p \quad s \quad v \quad w \quad . \]

**Notation** (for rules): The rule \( f_0 = (x_{00}, x_{01}, \ldots, x_{0n_0}) \), \( f_1 = (x_{10}, x_{11}, \ldots, x_{1n_1}) \), \( \ldots \), \( f_k = (x_{k0}, x_{k1}, \ldots, x_{kn_k}) \), \( h = \{(i, j), (i, j) \mid i \in \{0, 1, \ldots, k\} \text{ and } j \in \{1, \ldots, n_i\}\} \) may be abbreviated

\[
\begin{align*}
\frac{x_{00} w_{01} x_{01} \cdots w_{0n_0} x_{0n_0} \rightarrow x_{10} w_{11} x_{11} \cdots w_{1n_1} x_{1n_1} \cdots}{x_{k0} w_{kl} x_{kl} \cdots w_{kn_k} x_{kn_k}} \quad \text{or} \\
\frac{f_0 (w_{01}, \ldots, w_{0n_0}) \rightarrow f_1 (w_{11}, \ldots, w_{1n_1}) \cdots f_k (w_{kl}, \ldots, w_{kn_k})}{,}
\end{align*}
\]

omitting parentheses after \( f_i \) in case \( n_i = 0 \).

Thus, the rules of \( G_0 \) may also be written:

\[
\begin{align*}
\bar{s} \rightarrow \bar{n} \bar{p} a \bar{v} \bar{t} e , \bar{f} a \rightarrow \bar{w} , \bar{p} a \rightarrow \bigcirc , \bar{f} e \rightarrow \bigcirc , \bar{p} e \rightarrow \bar{d} \quad \text{or} \\
\bar{s} \rightarrow \bar{n} \bar{f}_2 (T) \bar{v} \bar{f}_1 (T) , \bar{f} a \rightarrow \bar{w} , \bar{p} a \rightarrow \bigcirc , \bar{f} e \rightarrow \bigcirc , \bar{p} e \rightarrow \bar{d} .
\end{align*}
\]

**Definition 2** (canonical representation): If \( G = (M, N, R_M, B, R, S) \) is a \( v^W G \), then \( c_G \) is a function, \( \text{dom}(c_G) = B^* \), \( \text{ran}(c_G) \subset (N \cup \{\}\}^* \), defined inductively:

\( c_G(\bigcirc) = \bigcirc \). If \( x \in B \) and \( X \in B^* \), then

\( c_G(\bar{x} X) = x', c_G(X) \).

Thus, \( c_G(\bar{n} \bar{w} \bar{v}) = n, \bar{w}, \bar{v}, \) and \( c_G(\bar{n} \bar{v} \bar{d}) = n, \bar{v}, \bar{d} \).
Definition 3: If $G = (M, N, R'_M, B, R, s)$ is a vWg and $E$ is a set, then a representation of $G$ (in $E$) is a generalized sequential machine (gsm) $D$ with input alphabet $E$ and output alphabet a subset of $N \cup \{,\}$. 

For example, $D_0$ is a representation of $G_0$, where

$$D_0 = (\{ y, z \}, \{ c, d, H, w, - \}, \{ d, n, v, w, ', ' \}, g, y, \{ y \})$$

(a gsm), where $g$ is given by:

<table>
<thead>
<tr>
<th>$g$</th>
<th>$y$</th>
<th>$z$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$c$</td>
<td>${ (y, v', ') }$</td>
<td>$\emptyset$</td>
</tr>
<tr>
<td>$d$</td>
<td>${ (y, d', ') }$</td>
<td>$\emptyset$</td>
</tr>
<tr>
<td>$H$</td>
<td>${ (z, h', ') }$</td>
<td>$\emptyset$</td>
</tr>
<tr>
<td>$w$</td>
<td>${ (z, w', ') }$</td>
<td>$\emptyset$</td>
</tr>
<tr>
<td>$-$</td>
<td>$\emptyset$</td>
<td>${ (y, \emptyset) }$</td>
</tr>
</tbody>
</table>

Definition 4 (substitution in rules): If $f = (x_0, x_1, \ldots, x_n) \in (N^*)^{n+1}$ and $(y_1, \ldots, y_n) \in (N^*)^n$, then $f(y_1, \ldots, y_n) = x_0 y_1 x_1 \ldots y_n x_n \in N^*$. (In case $n = 0$, understand $f = x_0$ as a nullary function.)

Definition 5 (universal assignment to metavariables): If $M, N, R'_M$ are as in definition 1, then

$$\hat{G}(M, N, R'_M) = \{ \hat{G} : M \rightarrow U \{ L((M, N, R'_M, W)) \mid W \in M \}$$

$$\mid \forall_{W \subseteq M} \hat{G}(W) \in L((M, N, R'_M, W)) \}.$$
Definition 6: If \( G = (M, N, R_M, B, R, s) \) is a vWG, \( r = (f_0, f_1, \ldots, f_k, h) \in R \), and \( c \in \hat{C}(M, N, R_M) \), then the strict rule of \( G \) corresponding to \((r, c)\) is

\[
\begin{align*}
  r_S(r, c) &= \frac{f_0(y_{01}, \ldots, y_{0n_0})}{y_{11}}, \ldots, \frac{f_k(y_{k1}, \ldots, y_{kn_k})}{y_{1n}} \quad \text{where} \quad \forall_{i=0}^k \forall_{j=1}^{n_i} y_{ij} = c(h(i, j)).
\end{align*}
\]

The set of strict rules of \( G \) is

\[
R_S(G) = \{ r_S(r, c) \mid r \in R \text{ and } c \in \hat{C}(M, N, R_M) \}.
\]

For example,

\[
R_S(G_0) = \{ \bar{s} \rightarrow \bar{n} f_2(y) \bar{v} f_4(y) \mid y \in \{ \bar{f}, \bar{p} \} \} \cup \{ \bar{f} a \rightarrow \bar{w}, \bar{p} a \rightarrow \bar{d} \}
\]

\[
= \{ \bar{s} \rightarrow \bar{n} f a \bar{v} f e, \bar{s} \rightarrow \bar{n} p a \bar{v} p e, f a \rightarrow \bar{w}, \bar{p} a \rightarrow \bar{d} \}, \text{ since}
\]

\[L((\{T\}, \{a, b, e, f, n, p, s, v, w\}, \{T \rightarrow f, T \rightarrow p\}, T)) = \{ \bar{f}, \bar{p} \}.
\]

Definition 7: If \( G = (M, N, R_M, B, R, s) \) is a vWG and \( D \) is a representation of \( G \), then the language specified by \( G \) is

\[
L(G) = \{ X \in B^* \mid \exists^*_G X \}, \text{ where } \exists^*_G \text{ is the reflexive-transitive closure of the binary relation } \exists_G \text{ in } (N^*)^*, \text{ which is defined by:}
\]

\[
X \exists^*_G Y \text{ if and only if } \exists\{U,V\} \subset (N^*)^* \text{ and } U = UXV \text{ and } Y = UYV
\]

and \((X' \rightarrow Y') \in R_S(G)\);

and the representation language specified by \((G, D)\) is

\[
L(G, D) = D^{-1}(\{ c_G(X) \mid X \in L(G) \})\]
For example,
\[ L(G_0) = \{ \overline{n} \overline{w} \overline{v}, \overline{n} \overline{v} \overline{d} \} \] and \[ L(G_0, D_0) = \{ H_{w,c}, H_{cd} \}. \]

**Definition 8:** If \( f = (x_0, x_1, \ldots, x_n) \in (N^*)^{n+1} \), then the weight of \( f \) is \( |f| = \sum_{i=0}^{n} |x_i| \). Note that the weight of \( f \) is the length of its abbreviation (2), ignoring metavariables.

**Definition 9:** A rule \((f_0, f_1, \ldots, f_k, h)\) of a vWg is context-sensitive (cs) if and only if \( |f_0| \leq \sum_{i=1}^{k} |f_i| \) and \( \forall_{w \in H} \text{card}([j | h(0, j) = w]) \leq \text{card}([i, j] | i > 0 \text{ and } h(i, j) = w) \). Note that a rule abbreviated as (2) is cs if and only if every metavariable occurs at least as often in the rhs as in the lhs and, ignoring metavariables, its rhs looks no shorter than its lhs.

**Definition 10:** A vWg is cs if and only if each of its rules is cs.

By way of example, note that the following rules fail to be cs:

\[ \text{abcw} \rightarrow \overline{aw} \overline{u}, \text{abcw} \rightarrow \overline{abu} \text{abcv}, \text{abcw} \rightarrow \overline{abuwv}, \]

where \( a, b, c \) are protovariables, \( U, V, W \) are metavariables.

The following is an obvious consequence of the above definitions.

**Theorem 0:** If \( G = (N, N, R_M, B, R, s) \) is a cs vWg and \((x_0 \rightarrow x_1 \ldots x_n) \in R_S(G)\), then \( |x_0| \leq \sum_{i=1}^{k} |x_i| \). If \( X = x_1 \ldots x_n \in (N^*)^* \), define (temporarily) \( [X] = \sum_{i=1}^{n} |x_i| \). If \( X_0 \overrightarrow{g} X_1 \overrightarrow{g} \ldots \overrightarrow{g} X_m \), then \( [X_0] \leq [X_1] \leq \ldots \leq [X_m] \).
Theorem 1: If G is a [cs] grammar, then there is a [cs] vWg G' and a representation D of G' with \( L(G', D) = L(G) \).

Lemma 1: If G = (M, N, R_M, B, R, s) is a [cs] vWg, then there is a [cs] vWg G' = (M', N', R_M', B', R', s') with \( \mathcal{W}_G \not\in L((M', N', R_M', W)) \) and \( L(G') = L(G) \).

Proof: By a familiar result, there is, given \( W \in M \), a csg \((M_W, N, R_W, W)\) with \( L((M_W, N, R_W, W)) = L((M, N, R_M, W)) \setminus \{ \mathcal{W} \} \).

Without loss of generality, suppose the \( M_W \) (\( W \in M \)) and \( M, N \) are pairwise disjoint, and that, in each rule of each \( R_W \), some element of \( M_W \) occurs on the lhs. Then the \( R_W \) are also pairwise disjoint. Define:

\[
M' = M, \\
N' = N, \\
B' = B, \\
s' = s, \\
R_M' = \bigcup \{ R_W \mid W \in M \}, \text{ and} \\
R' = \{ x_0 x_1 x_0 l \cdots x_i l x_{i+1} x_0 x_{i+2} x_0 \rightarrow x_0 x_1 x_2 x_1 l x_{i+3} x_{i+4} x_0 x_{i+2} x_0 \mid (x_0 x_1 x_2 x_1 l x_{i+3} x_{i+4} x_0 x_{i+2} x_0 \rightarrow x_0 x_1 x_2 x_1 l x_{i+3} x_{i+4} x_0 x_{i+2} x_0) \in R \}
\]

and \( \forall_{i=0}^{k} v_{i,j} \mid (w_i^j = W_{i,j} \text{ or } (\mathcal{W} \in L((H, N, R_H, W))) \text{ and } W_{i,j} = \mathcal{W}) \).
It is easy to see that $R_s(G') = R_s(G)$, whence, since $G'$ and $G$ have the same protovariables, basic strings, and starting string, $L(G') = L(G)$. Evidently, $G'$ is cs if and only if $G$ is.

**Theorem 2:** If $G$ is a vWG [resp. a cs vWG] and $D$ is a representation of $G$, then there is a nondeterministic tm [resp. lba] which accepts $L(G, D)$.

**Proof:** By construction, given $G = (M, N, R_M, B, R, s)$, of a nondeterministic tm [resp. lba] $A$, acting, by familiar techniques, on a six-track tape. In discussing the construction, it is convenient to make the following definitions:

(3) $c$ is a function, $\text{dom}(c) = ((N \cup M)^*)^*$, $\text{ran}(c) \subseteq (N \cup M \cup \{,\})^*$, 
$c(\otimes) = \otimes$, (inductively) if $x \in (N \cup M)^*$, 
$X \in ((N \cup M)^*)^*$, then $c(X) = x_1', c(X)$.

$\text{aug}$ is a function. If $X \in (N \cup \{,\})^*$, then $\text{aug}(X)$ is the six-track string with $X$ on track 1, blanks on tracks 2 through 6.

$D_a$ is a gsm, identical to $D$, except that $D_a$ outputs $\text{aug}(X)$ whenever $D$ outputs $X$.

$I$ is a function. If $X$ is a six-track string, then $I(X)$ is the part on track 1.
Immediately from the definitions, $c$ is one-to-one, $I(\text{aug}(X)) = X$, and $D_a(Y) = \{ \text{aug}(c(X)) \mid c(X) \in D(Y) \}$. In the construction to be given,
\[(4)\quad A \text{ accepts } T = \{ X \mid I(X) \in c(L(G)) \}.
\]
By definition, $D_a^{-1}(T) = \{ Y \mid D_a(Y) \cap T \neq \emptyset \}$. Therefore, by the present remarks, $D_a^{-1}(T) = \{ Y \mid \exists Z \in c(Z) \in c(L(G)) \text{ and } Z(2) \in D(Y) \} = L(G, D)$, and, by the familiar result that the set of languages accepted by tm [resp. lba] is closed under inverse gsm mappings, the construction of $A$ satisfying (4) is sufficient to prove the existence of the required acceptor of $L(G, D)$.

A produces on its track 1, given input $X$, a sequence $X_0, X_1, \ldots$ with $X_0 = I(X), \forall i c^{-1}(X_{i+1}) \geq c^{-1}(X_i)$ [and $|X_{i+1}| \leq |X_i|$]. $A$ accepts $X$ if and only if $c^{-1}(X_0) \in B^*$ and $\exists_n X_n = c(s)$. Therefore, $T = \{ X \mid I(X) \in c(L(G)) \}$. $A$ produces $X_{i+1}$ from $X_i$ by selecting (nondeterministically) a rule $(Y \rightarrow Z) \in R$ (consider the rule to be written in the form (2)). placing $c(Y)$ on track 3 and $c(Z)$ on track 2, each left-justified with $X_i$; generating (nondeterministically) a strict rule $(Y' \rightarrow Z') \in R_5(G)$ from $(Y \rightarrow Z)$ with $c(Y')$ on track 3 and $c(Z')$ on track 2, each still left-justified with $X_i$; shifting tracks 2 and 3 right (nondeterministically) $k$ squares ($k \geq 0$); and finally, in case $X_i = Uc(Z')V$ and $|U| = k$ and $(U = \varnothing$ or $U$ ends with '1') replacing $X_i$ on track 1 by $X_{i+1} = Uc(Y')V$. Tracks 1, 5, and 6 are used in the generation of $(Y' \rightarrow Z')$ from $(Y \rightarrow Z)$.
(See figure 1.) All strict rules of $G$ which could be used in a derivation $s \Rightarrow^* c^{-1}(X_0)$ are available for selection by $A$ at each stage,
since there is no restriction on its choices. [resp. since the only restrictions on its choices are $|c(Z')| + k \leq |X_0|$, $|c(Y')| + k \leq |X_0|$, $|c(Z)| \leq |X_0|$, and $|c(Y)| \leq |X_0|$, all of which follow (via theorem 0) in case $G$ is cs and

$$\forall_{W \in M} \diamond \not\in L(M, N, R, W),$$

from the obvious restriction $|c(Z')| + k \leq |X_1|$ on the applicability of $(Y' \rightarrow Z')$; and since lemma 1 shows there to be no loss of generality in supposing $G$ to satisfy (5).] Therefore, if $(s = X_0), X_1, \ldots, X_n$
is a derivation in $G$, then $A$ can produce the sequence $c(X_n), c(X_{n-1}),
\ldots, c(X_0)$ on its track 1, given input $\underline{\text{aug}}(c(X_n))$. I.e. $\{ X \mid I(X) \in c(L(G)) \} \subseteq T$.

Figure 1 is another outline of the algorithm embodied in $A$, with some further details. (In figure 1, T.i denotes the contents (non-blank) of track i.)

Figure 2 is an example of the operation of such an algorithm corresponding to the grammar $G_0$.

**Corollary (main result):** A language $L$ is type 0 [resp. type 1]
if and only if there is a $\text{vWg}$ [resp. a cs $\text{vWg}$] $G$ and a representation
$D$ of $G$ with $L = L(G, D)$.

**Proof:** By familiar results, directly from theorems 1 and 2.
**Strict** ≡ no element of $M$ occurs in $T.2$ or $T.3$

**proto** ≡ no element of $M$ occurs in $T.4$

match1 ≡ ($T.1 = U$, $T.2$ and $|U| = k$ and ($U = \emptyset$ or $U$ ends with $'$,))

figure 1.
figure 2.
Knuth and Bigelow (1967) have defined, in detail, a programming language for the class of deterministic stack automata (dsa). A program in this language has the general appearance of a one-block \texttt{algol} program, with \texttt{lisp}-style conditional statements. The language defined is a programming language in the sense that it permits an intuitively orderly, easily documentable, and reasonably compelling presentation of an algorithm. It is a language for the class of dsa in the sense that each program in it is mechanically translatable into a usual sort of specification of a dsa.

The language to be defined in the present paper will follow the general outlines of that of Knuth and Bigelow (1967). It will differ in detail from the latter to the end that each program will not specify a dsa, but rather a nondeterministic tm and a nondeterministic lba. It will also differ in detail in that some familiar 'programming techniques' for automata, namely variables and multiple tracks, are explicitly provided for in the language design. Another difference arises from the differing mathematical intents of the two papers. Knuth and Bigelow (1967) used their programming language to specify one particular dsa (diagonalizing the lba), whereas the present paper will use its programming language to show how to specify a tm or lba for each v.lg. I.e. the present paper requires a notation for tm- or lba- schemata.

Figure 3 exposes most of the ideas and constructions of the tm-lba programming language to be defined here.
begin

\(3.1\) \text{ tracks: } 2; \text{ alphabets: } (\{ a_i \mid i \in \{1, \ldots, n\} \mid , \}), (, +); \)

\(3.2\) \text{ variable } x \in (\{ a_i \mid i \in \{1, \ldots, n\} \mid , \});

\text{ procedure } \text{ rewind;}

\text{ begin } [ \not\Rightarrow R ; \Rightarrow L, \text{ repeat } ] \text{ end \text{ rewind;}}

\(3.3\) \{ \text{ procedure } \text{ bump}_i(\text{var});

\text{ begin } [ \text{ var } = a_i \Rightarrow \text{ var } \leftarrow a_{i+1} ] \text{ end \text{ bump}_i }

\(3.4\) \mid i \in \{1, \ldots, n-1\} \mid ; \};

\text{Choose } k \geq 1. \text{ Underline the first } k \text{ symbols with } ' \text{+}' . \)

\(3.5\) \text{ R, [ } \Rightarrow 2.+, \text{ R, repeat or \text{ rewind } ]},

\text{Check that the underlined symbols are all } a_i \text{ (i = 1 initially).} \)

\(3.6\) \text{ S: [ } 2.+ \Rightarrow [ 1.x \Rightarrow R ], \text{ repeat } ; \Rightarrow ],

\text{If } ' \text{+}' \text{ follows the underlined symbols and the } a_n \text{ have been checked, accept.} \)

\(3.7\) \[ \$$ \Rightarrow [ x = a_n \Rightarrow \text{ accept } ] ;

\text{If } a_{i+1} \text{ follows the underlined symbols, set } i \leftarrow i+1 . \)

\(3.8\) \{ 1.a_{i+1} \Rightarrow \text{ bump}_i(x) \mid i \in \{1, \ldots, n-1\} \mid ; \} ], \text{ L},

\text{Shift the } ' \text{+}' \text{ to underline the next group of } k \text{ symbols, then go to 3.6 .} \)

[ 1.x \Rightarrow \text{ go to } S ; \Rightarrow [ 2._\Rightarrow 2.+, [ \not\Rightarrow R ; 2._\Rightarrow R ; \Rightarrow L, \text{ repeat } ],

2._\Rightarrow R ;

\Rightarrow R, \text{ repeat } ], \text{ repeat } ]

end

Figure 3.
Figure 3 is a program schema which becomes a program upon fixing an integer \( n \geq 1 \) and symbols \( (a_1, a_2, \ldots, a_n) \). For such a fixed choice, it is a program specifying a \( TM \) and an LBA accepting \( \{ a_1^{k_1}a_2^{k_2}\ldots a_n^{k_n} | k \geq 1 \} \).

The portions of figure 3 in broken brackets ('<', '>') are commentary, and are ignored in parsing and translating the program.

The construction \( \{ X(u) \mid Y(u) \mid Z \} \), which occurs in lines 3.1, 3.2, 3.3-4, and 3.8, realizes the schematic character of the example. \( Y(u) \) is a formal statement (a predicate), possibly involving \( u \) as a free variable, whose content is fixed by the choice which turns the schema into a program. For example, in line 3.1, where \( u = i \) and \( Y(i) \equiv i \in \{ 1, \ldots, n \} \), the choice \( n = 3 \) would fix the content of \( Y(i) \equiv i \in \{ 1, 2, 3 \} \). For each choice turning the schema to a program, it must be the case that each expression \( Y(u) \) occurring in the program is satisfied by finitely many \( u \). \( X(u) \) is an expression which, for each choice of \( u \) satisfying \( Y(u) \), is a string of symbols of the programming language. \( Z \) is a string of symbols, used as a delimiter. If the choice turning the schema to a program fixes \( Y(u) \) so that it is satisfied only by \( \{ u_1, u_2, \ldots, u_m \} \), then \( \{ X(u) \mid Y(u) \mid Z \} \) is deemed, for purposes of the translation, to be replaced in the schema by \( X(u_1)ZX(u_2)Z \ldots ZX(u_m) \). The order of the solutions to \( Y(u) \) is only fixed if they are all integers, in which case they are taken in their natural order. (If an expression \( Y(u) \) with non-integral solutions is used in a schema, the schema generally fails to have a unique expression as a program, even when \( Y(u) \) is specified. It is intended that in this case the language be so used that the automata specified by various orderings of the solutions to \( Y(u) \) are strongly isomorphic. This is so in the main construction of the present paper.)
In the present example, suppose \( n = 3 \) and \((a_1, a_2, a_3) = (a, b, c)\) are fixed. Then \( \{ a_i | i \in \{1, \ldots, n\} \} \) in lines 3.1 and 3.2 is replaced by \( 'a, b, c' \). Also,

\[
\{ \text{procedure} \quad \text{bump}_i(\text{var}); \quad \text{begin} \quad [ \quad \text{var} = a_i \rightarrow \text{var} \leftarrow a_{i+1} \quad \text{end} \quad \text{bump}_i \quad | \quad i \in \{1, \ldots, n-1\} \quad | \quad ; \quad \} \]
\]
in lines 3.3-4 is replaced by

\[
'\text{procedure} \quad \text{bump}_1(\text{var}); \quad \text{begin} \quad [ \quad \text{var} = a \rightarrow \text{var} \leftarrow b \quad \text{end} \quad \text{bump}_1; \quad \text{procedure} \quad \text{bump}_2(\text{var}); \quad \text{begin} \quad [ \quad \text{var} = b \rightarrow \text{var} \leftarrow c \quad \text{end} \quad \text{bump}_2; \quad ' \]
\]

Also, \( \{ 1.a_{i+1} \rightarrow \text{bump}_i(x) \mid i \in \{1,\ldots,n-1\} \mid ; \} \)
in line 3.8 is replaced by \( '1.b \rightarrow \text{bump}_1(x); 1.c \rightarrow \text{bump}_2(x)' \).

From a logical point of view, the replacements just described must be made prior to any steps in the translation of the program, since, until the replacements are made, there is no program, only a schema. Furthermore, elimination of the \( \{ X \mid Y \mid Z \} \) construction may not be sufficient to specify the program. For example, it is also necessary in the present case to replace \( 'a_n' \) in line 3.7 by \( 'c' \).

The first step of the translation process itself is the elimination of the declared procedures and of all references to them. As in Knuth and Bigelow (1967), the procedures are really macros. They are eliminated by being copied, with arguments suitably replaced, in place of their calls.
In the present example, still supposing \((a_1, \ldots, a_n) = (a, b, c)\),
'rewind' is replaced in line 3.5 by '[ \emptyset \Rightarrow R ; \Rightarrow L, \text{repeat } ]',
'bump_1(x)' is replaced by '[ x = a \Rightarrow x \leftarrow b ]', and 'bump_2(x)' is
replaced by '[ x = b \Rightarrow x \leftarrow c ]'. For this example, then, figure 6
is the program to be translated.

\begin
\begin{align}
\langle 4.1 \rangle & \quad \text{tracks: 2; alphabets: (a, b, c), (_, +)}; \\
\langle 4.2 \rangle & \quad \text{variable } x \in (a, b, c); \\
\langle 4.3 \rangle & \quad R, [ \Rightarrow 2.+, R, \text{repeat or } [ \emptyset \Rightarrow R ; \Rightarrow L, \text{repeat } ] ], \\
\langle 4.4 \rangle & \quad S: [ 2.+ \Rightarrow [ 1.x \Rightarrow R ], \text{repeat } ; \Rightarrow ], \\
\langle 4.5 \rangle & \quad [ \emptyset \Rightarrow [ x = c \Rightarrow \text{accept } ] ; \\
\langle 4.6 \rangle & \quad 1.b \Rightarrow [ x = a \Rightarrow x \leftarrow b ] ; \\
\langle 4.7 \rangle & \quad 1.c \Rightarrow [ x = b \Rightarrow x \leftarrow c ] ), L, \\
\langle 4.8 \rangle & \quad [ 1.x \Rightarrow \text{go to } S ; \Rightarrow [ 2._- \Rightarrow 2.+, [ \emptyset \Rightarrow R ; 2._- \Rightarrow R ; \Rightarrow L, \text{repeat } ] ], 2._-, R ; \\
\langle 4.9 \rangle & \quad \Rightarrow R, \text{repeat } ], \text{repeat } ] \\
\langle 4.10 \rangle & \quad \end
\end{align}
\end

Figure 4.

The remaining declarations (in lines 4.1 and 4.2) specify that the
machine's tape is to be considered as divided into two tracks, one to be
marked with the symbols \{a, b, c\}, the other with \{_, +\}, and that
its finite control is to be used to store as the value of a variable \(x\)
an element of \{a, b, c\}, initially 'a', the first one listed.
By convention, the input is the initial contents of track 1 (the one whose alphabet is \{a, b, c\}), and the remaining track is initially to be filled with the first symbol of its alphabet, '1'. The left- and right-end-marks, '€' and '§', respectively, do not lie on any track, but each occupies one whole tape square. The initial scan point is '€'.

The rest of the program (after the declarations) consists of a list of actions of one sort or another, separated by commas. The basic flow of control in the program is from the first of these ('R') to the second ('[ => 2.* ... ])'), and so on. There are, however, labels, such as 'S' in line 4.4, and jumps, such as 'go to S' in line 4.8, which modify the basic flow in an obvious way.

The square-bracketed portions of the program, which are lisp-style conditional statements, provide a further modification of the control flow. These conditional statements consist of a sequence of expressions, each dominated by '=>', separated by semi-colons. The portion of each such expression left of '=>' is a condition which may be satisfied or not. The action of the whole conditional statement is to examine the conditions, one at a time, from left to right, until one which is satisfied is found; then to perform the list of actions, which may be empty, right of the '=>' associated with that condition; then to go on with the next action following the whole conditional statement. (But see the description of 'repeat', below.) If no condition is satisfied, the effect is that the machine halts without accepting the input.

2. This convention is adopted for the sake of the present example. Its effect is incorporated into the design of A (see theorem 2) in the main construction, so that it need not be assumed there.
Some possible conditions are: that a particular symbol is being scanned ('ε' in line 4.3, '∉' in line 4.5); that the tape square being scanned has a particular symbol on a particular track ('2.+ ' in line 4.1, '1.b' in line 4.6); that the tape square being scanned has, on a particular track, the symbol which is the current value of a particular variable ('1.x' in line 4.4); that a particular symbol is the current value of a particular variable ('x = c' in line 4.5); the empty condition, which is always satisfied (twice in line 4.3, four places elsewhere).

An additional effect on the flow of control due to conditional statements is provided by the atomic action 'repeat'. Its action is to cause the smallest conditional statement of which it is a constituent to be performed again.

Additional atomic actions are: to write a particular symbol on a particular track of the currently scanned tape square ('2.+ ' in lines 4.3 and 4.8, '2._ ' in line 4.9); to shift the scan point left or right ('L' and 'R' respectively); to set the current value of a particular variable ('x ← b' in line 4.6); to halt the machine, accepting the input ('accept' in line 4.5).

The reader should now be able to verify the following descriptions: The effect of the inner nested conditional on line 4.3 is to position the scan point just right of 'ε'. The effect of the innermost nested conditional on line 4.8 is to position the scan point just right of the rightmost square which is left of or at the present scan point, and which has '_ ' on track 2; or, if there is no such square, then just right of 'ε'. 
The effect of the intermediately nested conditional on lines 4,8-10 is to replace the leftmost '_' on track 2 which is at or right of the present scan point with a '+', and to replace the leftmost '+' on track 2 which is at or left of the new '+' with a '_' (Recall that only '_' and '+' occur on track 2.), all unless there is no '_' at or right of the present scan point, in which case the effect is to fail to accept the input.

(In the lba translation, the failure is due to an 'attempted' right shift scanning '$$. In the tm translation, the failure is due to an interminably repeated right shift, since '$' is the natural tape blank.)

The effect of the conditional in lines 4,5-7 is given by the following table:

<table>
<thead>
<tr>
<th>value of x</th>
<th>(a, _)</th>
<th>(a, +)</th>
<th>(b, _)</th>
<th>(b, +)</th>
<th>(c, _)</th>
<th>(c, +)</th>
<th>$</th>
<th>$$</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>fail</td>
<td>fail</td>
<td>x &lt;-- b</td>
<td>x &lt;-- b</td>
<td>fail</td>
<td>fail</td>
<td>fail</td>
<td>fail</td>
</tr>
<tr>
<td>b</td>
<td>fail</td>
<td>fail</td>
<td>fail</td>
<td>fail</td>
<td>x &lt;-- c</td>
<td>x &lt;-- c</td>
<td>fail</td>
<td>fail</td>
</tr>
<tr>
<td>c</td>
<td>fail</td>
<td>fail</td>
<td>fail</td>
<td>fail</td>
<td>fail</td>
<td>fail</td>
<td>fail</td>
<td>accept</td>
</tr>
</tbody>
</table>

The nondeterminism of the machine specified by this program is due to the 'or' in line 4,3. In general, an action can be a list of actions separated by 'or's, in which case any of the listed actions may be chosen. In particular, the effect of line 4,3 (noting that it is at the beginning of the program) is to write one or more '+'s on track 2, beginning at its left end, then to position the scan point just right of '$', i.e. at the first '+' written.

The reader should now be able to verify the descriptions given as commentary to figure 3, and that it specifies an acceptor for \( \{ a_1^{k_1}a_2^{k_2} \cdots a_n^{k_n} \mid k \geq 1 \} \).
the programming language, formally

The present section specifies which strings of symbols are (syntactically) valid

(i) program schemata,
(ii) programs (with procedures), and
(iii) procedure-free programs,

and what tm (resp. lba) are specified by such strings. Logically, the definition for (iii) is prior to that for (ii) and similarly (ii) prior to (i). The definitions are presented here in the reverse of this logical order, to provide better motivation.

Definition 11: A program schema \( S \) depending on formal parameter \( P \) is valid over a set \( \mathbb{P} \) if and only if each choice of \( P \in \mathbb{P} \) turns \( S \) into a valid program (with procedures) \( X \) by the process outlined in the preceding section. For such \( S, \mathbb{P}, X \), the tm (resp. lba) corresponding to \( P \in \mathbb{P} \) specified by \( S \) is the tm (resp. lba) specified by \( X \).

For example, if \( (a_1, a_2, \ldots) \) is some fixed non-repeating sequence of symbols, then figure 3 is a program schema depending on formal parameter \( n \) valid over the set of positive whole numbers. Also: the main construction of the present paper is a program schema depending on formal parameter \( G \) (asserted to be) valid over any set of \( vlg \).

The lack of formality in definition 11 ('Turns into' is ill-defined.) is justified by the fact that it applies to objects explicitly presented, indeed, for the main purpose of the present paper, to just one such object, namely the program schema depending on \( G \) for the acceptor \( A \) of theorem 2.
The alternative to this style of presentation is the formal introduction of another metalinguistic level, the details of which would be more distracting than enlightening.

Knuth and Bigelow (1967) give a syntax for procedure declarations and statements (calls) which requires only changes in character set to serve here, and which will not be repeated here. It is sufficient to note that such a syntax serves to ensure that the procedure constructs have the general appearance of the corresponding ALGOL 60 constructs, and have the following properties:

Each procedure call occurs in a textual setting in which a <statement list> is valid. (See below. The syntax of <simple statement> is expanded to include procedure calls.) Each actual parameter of each procedure call is a string of symbols in which commas only occur within properly nested parentheses and brackets, and in which all parentheses and brackets are properly nested. The actual parameters of each procedure call agree in number with the formal parameters of the associated procedure declaration, and, if the actual parameters are substituted for the corresponding formal parameters throughout the body of the procedure declaration, the resulting text between `begin' and `end' is a valid <statement list>.

Definition 12: A program (with procedures) X is valid if and only if the following transformation process terminates when applied to X, with the result a valid procedure-free program Y. For such X,Y, the tm [resp. lba] specified by X is the tm [resp. lba] specified by Y.
Transformation Process (Elimination of procedure constructs):

Step 1: If there are no procedure calls in the text (as transformed so far), erase all procedure declarations and halt. Otherwise go on to step 2.

Step 2: Transform the text by copying the appropriate procedure body (between 'begin' and 'end'), with actual parameters substituted throughout for formal parameters, in place of the first procedure call in the text. Go on to step 3.

Step 3: Replace each label and each reference to it throughout the modified procedure body just copied in step 2 by a new label (not occurring elsewhere in the text). Return to step 1.

The selection and transformation process implicit in definitions 11 and 12 is exemplified in the preceding section: If \((a_1, a_2, a_3, \ldots) = (a, b, c, \ldots)\), then the \(tm\) [resp. \(lba\)] corresponding to \(n = 3\) specified by figure 3 (a program schema) is the \(tm\) [resp. \(lba\)] specified by figure 4 (a procedure-free program).

The remainder of the present section defines (syntactic) validity for procedure-free programs, and defines a transformation of valid procedure-free programs into quadruples specifying \(tm\) [resp. \(lba\)] in the manner indicated in the introduction to the present paper. Validity is defined in terms of a backus-form grammar with restrictions (stated in prose). The transformation to quadruples is defined in terms of three functions, whose arguments are strings of programming language symbols and some bookkeeping quantities. These restrictions and function definitions are interspersed with the backus-form syntax equations.
An informal description of the functions used to define the transformation to quadruples follows:

quad\((X, p, q, s)\) is the set of quadruples corresponding to the occurrence of program string \(X\) starting at position number \(p\) (in the program string), ending at position number \(q\), with \(s\) the 'first new available' position number just left of \(X\).

Quad\((X, p, q, s, E)\) is the set of quadruples corresponding to \(X, p, q, s\) as for quad. \(X\) must be a part of a conditional statement (in fact, a \(<\text{conditional tail}>\)), and \(E\) is the set of conditions specified left of \(X\).

next\((X, s)\) is the 'first new available' position number right of the program string \(X\), supposing \(s\) to be the 'first new available' position number just left of \(X\).

No formal statement of the possible values of the arguments of these functions needs to be made, since the functions are usefully evaluated only in response to the requirements of definition 13 and their 'recursive calls' on one another. For the same reason, the order of their evaluation (with various arguments) in transforming a specific valid procedure-free program is, to some extent, fixed. Accordingly, the reader may wish to regard them as specifying a mechanical translation procedure (dynamic), as well as a transformation (static) of strings to sets of quadruples.

The following definition is given out of order to provide better motivation. Logically, the backus-form grammar and the definition of the three functions described above are prior to it.
Definition 13: A procedure-free program is valid if and only if it is a terminal production of \langle program \rangle. If a \langle program \rangle has \langle statements \rangle \ L \ and \ \langle declarations \rangle specifying variable set \ \mathbb{V} \ and initial variable \ v_0, then it specifies the tm \ [\text{resp. lba}] \ with quadruples \ \text{quad}(L, 1, -1, 2) [3] \ whose states are \ \{ -1, 0, 1, \ldots, \text{next}(L, 2) - 1 \} \times \mathbb{V}, \ whose initial state is \ \langle 1, v_0 \rangle, \ and whose set of accepting states is \ \{0\} \times \mathbb{V}.

\langle program \rangle \rightarrow \text{begin} \ \langle declarations \rangle \ \langle statements \rangle \ \text{end}
\langle declarations \rangle \rightarrow \langle track declaration \rangle \ \langle alphabet declaration \rangle
\langle variable declarations \rangle \ \langle track variable declaration \rangle
\langle class declarations \rangle
\langle statements \rangle \rightarrow \langle statement list \rangle
\langle track declaration \rangle \rightarrow \text{tracks} : \langle unsigned integer \rangle ;

For the remainder of the present description, the value of \langle unsigned integer \rangle\ in the \langle track declaration \rangle will be referred to as \ k. 

\langle alphabet declaration \rangle \rightarrow \text{alphabets} : \langle alphabets \rangle ;
\langle alphabets \rangle \rightarrow \langle repeated alphabet \rangle \ | \ \langle alphabets \rangle ,
\langle repeated alphabet \rangle
\langle repeated alphabet \rangle \rightarrow \langle set \rangle \ | \ \langle unsigned integer \rangle \times \langle set \rangle

3. The usefulness of '1' and '2' here should be clear from the informal description of \text{quad}. The '-1' is a technical device to permit \text{quad} \ to be applied even to strings including the end of the program. No quadruples corresponding to moves from states of the form \langle -1, v \rangle \ are generated by definition 13, so the effect of the '-1' on control flow is that 'falling through' the program is a failure to accept the input.
The alphabet specified by the \langle alphabet declaration \rangle

\[
\text{alphabets} : \quad i_1 \times (a_{11}, a_{12}, \ldots, a_{1j_l}), \quad i_2 \times (a_{21}, a_{22}, \ldots, a_{2j_2}), \ldots, \quad i_z \times (a_{z1}, a_{z2}, \ldots, a_{zj_z});
\]

is (If an 'i_e x' is omitted, '1 x' is assumed):

\[
\begin{align*}
&\text{\underline{i_1 times}} \\
&\{\$\}, \{\$\} \cup (\{a_{11}, a_{12}, \ldots, a_{1j_l}\} \times \ldots \times \{a_{11}, a_{12}, \ldots, a_{1j_l}\}) \\
&\text{\underline{i_2 times}} \\
&\times (a_{21}, a_{22}, \ldots, a_{2j_2}) \times \ldots \times (a_{21}, a_{22}, \ldots, a_{2j_2}) \\
&\text{\underline{i_z times}} \\
&\times (a_{z1}, a_{z2}, \ldots, a_{zj_z}) \times \ldots \times (a_{z1}, a_{z2}, \ldots, a_{zj_z}) \\
\end{align*}
\]

It is required that \( \sum_{c=1}^{z} i_c = k \). For the remainder of the present description, the alphabet specified will be referred to as \( A = \{\$\}, \{\$\} \cup (A_1 \times A_2 \times \ldots \times A_k) \).

\[
\langle \text{variable declarations} \rangle \rightarrow \langle \text{empty} \rangle \mid \langle \text{variable declaration} \rangle
\]

\[
\langle \text{variable declarations} \rangle
\]

\[
\langle \text{variable declaration} \rangle \rightarrow \text{variable} \ \langle \text{identifier} \rangle \ e \ \langle \text{set} \rangle;
\]

\[
\langle \text{track variable declaration} \rangle \rightarrow \text{track variable} \ \langle \text{identifiers} \rangle;
\]

The variable set specified by the \langle variable declarations \rangle and \langle track variable declaration \rangle
variable $x_1, x_2, \ldots, x_{i_1} \in (a_{11}, a_{12}, \ldots, a_{1j_1})$

variable $x_{i_1+1}, x_{i_1+2}, \ldots, x_{i_2} \in (a_{21}, a_{22}, \ldots, a_{2j_2})$

variable $x_{i_2+1}, x_{i_2+2}, \ldots, x_{i_3} \in (a_{31}, a_{32}, \ldots, a_{3j_3})$

track variable $t_1, t_2, \ldots, t_n$

is:

\[
\frac{1}{i_1 \text{ times}} \frac{1}{i_2 \text{ times}} \frac{1}{i_3 \text{ times}} \frac{1}{n \text{ times}} \frac{1}{m \text{ times}} \\
\{a_{11}, a_{12}, \ldots, a_{1j_1}\} \times \ldots \times \{a_{11}, a_{12}, \ldots, a_{1j_1}\} \\
\times \{a_{21}, a_{22}, \ldots, a_{2j_2}\} \times \ldots \times \{a_{21}, a_{22}, \ldots, a_{2j_2}\} \\
\times \{a_{31}, a_{32}, \ldots, a_{3j_3}\} \times \ldots \times \{a_{31}, a_{32}, \ldots, a_{3j_3}\} \\
\times \{1, 2, \ldots, k\} \times \ldots \times \{1, 2, \ldots, k\} 
\]

For the remainder of the present description, the variable set specified will be referred to as $X = X_1 \times X_2 \times \ldots \times X_m \times \{1, 2, \ldots, k\}^n$, and the variables declared referred to as $x_1, x_2, \ldots, x_m, t_1, t_2, \ldots, t_n$.

The initial variable specified by the same <variable declarations> and <track variable declaration> is:

\[
\frac{1}{i_1 \text{ times}} \frac{1}{i_2 \text{ times}} \frac{1}{i_3 \text{ times}} \frac{1}{n \text{ times}} \\
(a_{11}, \ldots, a_{11}, a_{21}, \ldots, a_{21}, \ldots, a_{2j_2}, \ldots, a_{2j_2}, 1, \ldots, 1) 
\]

<class declarations> → <empty> | <class declaration>

<class declarations>

<class declaration> → class <identifiers> = <set> ;
The class set specified by the <class declarations>:

\[
\text{class } K_1, K_2, \ldots, K_{i_1} = (a_{11}, a_{12}, \ldots, a_{1j_1}) ; \\
\text{class } K_{i_1+1}, K_{i_1+2}, \ldots, K_{i_2} = (a_{21}, a_{22}, \ldots, a_{2j_2}) ; \ldots ; \\
\text{class } K_{i_{z-1}+1}, K_{i_{z-1}+2}, \ldots, K_{i_z} = (a_{z1}, a_{z2}, \ldots, a_{zj_z}) ;
\]

is:

\[
\begin{array}{c}
\{a_{11}, a_{12}, \ldots, a_{1j_1}\} \times \ldots \times \{a_{11}, a_{12}, \ldots, a_{1j_1}\} \\
\text{i_1 times}
\end{array}
\]

\[
\begin{array}{c}
\{a_{21}, a_{22}, \ldots, a_{2j_2}\} \times \ldots \times \{a_{21}, a_{22}, \ldots, a_{2j_2}\} \\
\text{i_2 times}
\end{array}
\]

\[
\begin{array}{c}
\{a_{z1}, a_{z2}, \ldots, a_{zj_z}\} \times \ldots \times \{a_{z1}, a_{z2}, \ldots, a_{zj_z}\} \\
\text{m_1 times}
\end{array}
\]

\[
\begin{array}{c}
\{a_{z1}, a_{z2}, \ldots, a_{zj_z}\} \times \ldots \times \{a_{z1}, a_{z2}, \ldots, a_{zj_z}\} \\
\text{m_z times}
\end{array}
\]

For the remainder of the present description, the class set specified will be referred to as \( K_1 \times K_2 \times \ldots \times K_{m_1} \), and the class variables declared referred to as \( K_1, K_2, \ldots, K_{m_1} \).

\(<\text{identifiers}> \rightarrow <\text{identifier}> | <\text{identifier}> , <\text{identifiers}>\)

No <identifier> is permitted to occur more than once in the <declarations>.

\(<\text{statement list}> \rightarrow <\text{nondeterministic list}> | <\text{nondeterministic list}> , <\text{statement list}>\)
If \( L_1 = N \), \( L_2 \), \( N \) is a \( \langle \text{nondeterministic list} \rangle \), and \( L_2 \) is a \( \langle \text{statement list} \rangle \), then

\[
\text{quad}(L_1, p, q, s) = \text{quad}(N, p, s, s+1)
\]
\[
\text{quad}(L_2, s, q, \text{next}(N, s+1)) \quad \text{and}
\]
\[
\text{next}(L_1, s) = \text{next}(L_2, \text{next}(N, s+1)).
\]

\( \langle \text{nondeterministic list} \rangle \rightarrow \langle \text{statement} \rangle | \langle \text{statement} \rangle \text{ or } \langle \text{nondeterministic list} \rangle \)

If \( N_1 = S \text{ or } N_2 \), \( S \) is a \( \langle \text{statement} \rangle \), and \( N_2 \) is a \( \langle \text{nondeterministic list} \rangle \), then

\[
\text{quad}(N_1, p, q, s) = \{(p,v), a, a, (s,v) | a \in A \text{ and } v \in \mathcal{V} \text{ and } s \in \{s, s+1\}\} \cup \text{quad}(S, s, q, s+2)
\]
\[
\text{quad}(N_2, s+1, q, \text{next}(S, s+2)) \quad \text{and}
\]
\[
\text{next}(N_1, s) = \text{next}(N_2, \text{next}(S, s+2)).
\]

\( \langle \text{statement} \rangle \rightarrow \langle \text{identifier} \rangle : \langle \text{statement} \rangle | (\langle \text{statement list} \rangle) | [\langle \text{conditional tail} \rangle | \langle \text{simple statement} \rangle \]

In the first case, the \( \langle \text{identifier} \rangle \), which must not occur anywhere else in the \( \langle \text{program} \rangle \) except in a \( \langle \text{jump} \rangle \), is said to be a \( (\text{valid}) \) \text{ label}.

If \( S_1 = I :: S_2 \), \( I \) is an \( \langle \text{identifier} \rangle \), and \( S_2 \) is a \( \langle \text{statement list} \rangle \), then

\[
\text{quad}(S_1, p, q, s) = \text{quad}(S_2, p, q, s) \quad \text{and} \quad \text{next}(S_1, s) = \text{next}(S_2, s).
\]

In this case, any state \( (p, v) \), \( v \in \mathcal{V} \), is said to correspond to \( I \).
If $S = \text{'(1 L')}$ and $L$ is a $\langle$statement list$\rangle$, then
\[
\text{quad}(S, p, q, s) = \text{quad}(L, p, q, s) \quad \text{and} \quad \text{next}(S, s) = \text{next}(L, s).
\]

If $S = \text{'[1 T}$ and $T$ is a $\langle$conditional tail$\rangle$, then
\[
\text{quad}(S, p, q, s) = \text{Quad}(T, p, q, s, \emptyset) \quad \text{and} \quad \\
\text{next}(S, s) = \text{next}(T, s).
\]

$\langle$conditional tail$\rangle \rightarrow \, | \, ; \, | \langle$conditional tail$\rangle$

$\langle$condition$\rangle \Rightarrow \langle$statement list$\rangle \langle$conditional tail$\rangle$

$\text{Quad}(\text{'}\}, p, q, s, E) = \emptyset$ and $\text{next}(\text{'}\}, s) = s$

If $T_1 = \text{'1 T}_2$ and $T_2$ is a $\langle$conditional tail$\rangle$, then
\[
\text{Quad}(T_1, p, q, s, E) = \text{Quad}(T_2, p, q, s, E) \quad \text{and} \quad \\
\text{next}(T_1, s) = \text{next}(T_2, s).
\]

If $T_1 = \text{'C }\Rightarrow\text{'1 T}_2$, $C$ is a $\langle$condition$\rangle$, $L$ is a $\langle$statement list$\rangle$, and $T_2$ is a $\langle$conditional tail$\rangle$, then
\[
\text{Quad}(T_1, p, q, s, E) = \{(a, v), a, a, (s, v) \mid a, v \in \Delta \quad \text{and} \quad \\
(\forall b, x_i, t_i, s_i, \ldots, t_n, s_n, E) \in \text{Quad}(L, s, q, s+1) \quad \text{U} \\
\text{Quad}(T_2, p, q, \text{next}(L, s+1), E \cup \text{D}(C)) \quad \text{and} \\
\text{next}(T_1, s) = \text{next}(T_2, \text{next}(L, s+1)), \text{ where} \\
\text{D}(C) = \{(a, v) \mid a \in \Delta \quad \text{and} \quad v = (x_1, \ldots, x_m, t_1, \ldots, t_n) \in \mathcal{V} \\
\text{and} \quad P_0(C) \} \quad \text{and} \quad P_0 \text{ is given below, in table 1.}
\langle \text{condition} \rangle \rightarrow \langle \text{identifier} \rangle \langle \text{relation} \rangle \langle \text{expression} \rangle |

\langle \text{track expression} \rangle \cdot \langle \text{class expression} \rangle |

\langle \text{whole tape symbol} \rangle \mid \langle \text{empty} \rangle

In the first case: (i) If the \langle \text{identifier} \rangle occurred in a \langle \text{track variable declaration} \rangle, then the \langle \text{relation} \rangle must be '=' or '≠', and the \langle \text{expression} \rangle a \langle \text{track expression} \rangle. (ii) If the \langle \text{identifier} \rangle occurred in a \langle \text{variable declaration} \rangle, then: If the \langle \text{expression} \rangle is not a \langle \text{symbol expression} \rangle, it must be a \langle \text{class expression} \rangle and the \langle \text{relation} \rangle must be '=' or '≠'. If the \langle \text{expression} \rangle is a \langle \text{symbol expression} \rangle, the \langle \text{relation} \rangle must be '=' or '≠'. (i) or (ii) must be satisfied.

| C | \text{c}_i = j | \text{c}_i ≠ j | \text{c}_i = \text{c}_j | \text{c}_i ≠ \text{c}_j | \text{x}_i ∈ \hat{K}_j | \text{x}_i \not\in \hat{K}_j | \text{x}_i = c |

Table 2.
\[\text{<store>} \rightarrow \text{<identifier>} \leftarrow \text{<symbol expression>} | \text{<identifier>}
\]
\[\leftarrow \text{<track expression>} . | \text{<identifier>} \leftarrow \text{<track expression>}
\]

In the first two cases, the \text{<identifier>} must have occurred in a \text{<variable declaration>}. In the third case, the \text{<identifier>} must have occurred in a \text{<track variable declaration>}.

If \( V \) is a \text{<store>}, then

\[
\text{quad}(V, p, q, s) = \{((v, (x_1, \ldots, x_m, t_1, \ldots, t_n)), a, a, (q, (y_1, \ldots, y_m, u_1, \ldots, u_n))) \mid a \in A \text{ and } \forall_{e=1}^{m} \{x_e, y_e\} \subseteq X \text{ and } \forall_{e=1}^{n} \{t_e, u_e\} \subseteq \{1, \ldots, k\} \text{ and } P_2(V)\},
\]

where \( P_2 \) is given in table 3.

<table>
<thead>
<tr>
<th>( V )</th>
<th>( P_2(V) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x_i \leftarrow c )</td>
<td>( y_i = c )</td>

<td>( a = (a_1, \ldots, a_k) ) and ( y_i = a_j )</td>
</tr>
<tr>
<td>( x_i \leftarrow t_j )</td>
<td>( a = (a_1, \ldots, a_k) ) and ( y_i = a_{t_j} )</td>
</tr>
<tr>
<td>( e_i \leftarrow j )</td>
<td>( u_i = j )</td>
</tr>
<tr>
<td>( e_i \leftarrow t_j )</td>
<td>( u_i = t_j )</td>
</tr>
</tbody>
</table>

Table 3.

\[\text{<shift>} \rightarrow L | R\]

If \( M \) is a \text{<shift>}, then

\[
\text{quad}(M, p, q, s) = \{((v, v), a, M, (q, v)) \mid a \in A \text{ and } v \in \mathcal{V}
\]

\[\text{[and } M = 'L' \Rightarrow a \neq 'i' \text{ and } M = 'R' \Rightarrow a \neq 'i' \# \text{]}\}.
\]
\[ \langle \text{jump} \rangle \rightarrow \langle \text{empty} \rangle \mid \text{accept} \mid \text{go to} \langle \text{identifier} \rangle \mid \text{repeat} \]

The \langle identifier \rangle following 'go to' must be a valid label. (See syntax for \langle statement \rangle.)

'repeat' must lie within a \langle conditional statement \rangle.

If \( J \) is a \langle jump \rangle, then

\[
\text{quad}(J, p, q, s) = \{(p, v), a, a, (r, v) \mid a \in \mathcal{A} \text{ and } v \in \mathcal{V} \},
\]

where:

If \( J = \Diamond \), then \( r = q \).

If \( J = \text{accept} \), then \( r = 0 \).

If \( J = \text{go to} \), then necessarily, in the evaluation of the function \text{quad} applied to the program, the function \text{quad} is applied exactly once with first argument \( I:'S \) for some \langle simple statement \rangle \( S \). \( r \) is the second argument of \text{quad} in that application.

If \( J = \text{repeat} \), then necessarily \( J \) lies in some \langle conditional tail \rangle. Let \( T \) be the shortest \langle conditional tail \rangle including (the present instance of) \( J \). In the evaluation of the function \text{quad} applied to the program, the function \text{Cquad} is applied with first argument \( T \). \( r \) is the second argument of \text{Cquad} in its application to (the present instance of) \( T \).

\[ \langle \text{expression} \rangle \rightarrow \langle \text{class expression} \rangle \mid \langle \text{track expression} \rangle \]

\[ \langle \text{class expression} \rangle \rightarrow \langle \text{identifier} \rangle \mid \langle \text{symbol expression} \rangle \]

If the \langle identifier \rangle is not a \langle symbol expression \rangle, it must have occurred in a \langle class declaration \rangle.
\[
\text{〈symbol expression〉} \rightarrow \text{〈symbol〉} \mid \text{〈identifier〉}
\]

The 〈identifier〉 must have occurred in a 〈variable declaration〉.

\[
\text{〈track expression〉} \rightarrow \text{〈unsigned integer〉} \mid \text{〈identifier〉}
\]

The 〈unsigned integer〉 must have a value \( \in \{1, \ldots, k\} \). The 〈identifier〉 must have occurred in a 〈track variable declaration〉.

\[
\text{〈whole tape symbol〉} \rightarrow \epsilon \mid \$ \mid \text{〈set〉}
\]

The 〈set〉 must have \( k \) components.

\[
\text{〈relation〉} \rightarrow = \mid \neq \mid \epsilon \mid \ell
\]

\[
\text{〈set〉} \rightarrow (\text{〈symbols〉})
\]

\[
\text{〈symbols〉} \rightarrow \text{〈symbol〉} \mid \text{〈symbol〉}, \text{〈symbols〉}
\]

The syntax for 〈symbol〉 varies with the application.

The syntax for 〈identifier〉, 〈unsigned integer〉, and 〈empty〉 is usual.

Figures 5 and 6 illustrate the application of definition 13 to the procedure-free program of figure 4. In figure 5, the program is marked so as to show the program positions corresponding to the first component of the tm (resp. lb) states. Figure 6 shows the quadruples of which the tm (resp. lb) corresponding to figure 5 is composed, tabulated as a 'move function'. Entries marked '[]' are to be included (resp. omitted). The table is abbreviated, showing the second (variable set) component of a state only where pertinent, and omitting tape symbols in the body of the table unless they indicate a change in tape contents.

Figure 6. (page 2/2)
The present section consists mainly of a program schema depending on $G = (M, N, R_M, B, R, s)$, a $\nu Wg$, in the language of the preceding sections.

Even for fixed $G$, the ultimate transformations of the schema into $tm$ and $lba$ will differ. Accordingly, as a schema, it has two sets of properties. Matter (in the commentary) enclosed in square brackets refers to its properties as an $lba$-language program schema.

Variations on $'y$ is pushed right on track $t$ to make room for $x \mapsto \hat{x}$ occur in the commentary. Their meaning is: 'If the contents of track $t$ is $xy(\_)^k$ and $|\hat{x}| \geq |x|$, then the present action is (to fail if $|\hat{x}| - |x| > k$, otherwise) to place $\hat{xy}(\_)^{\hat{R}}$ on track $t$, where $\hat{R} = \max \{0, k - (|\hat{x}| - |x|)\}$.'

Some other notations used in this and the following section are:

T.i denotes (as in preceding sections) the string on track $i$ left of the leftmost occurrence on track 1 of $'_'$.

If $x$ is (declared to be) a variable, then $(x)$ denotes its value.

The notations $c$ and $I$ (as at (3)) are retained.

```
begin
tracks: 6;
alphabets: 6 \times (\{ a | a \in \{_, +\} U M U N \text{ or } a = , | , \}) U
variable x1, x2 \in (\{ a | a \in \{_, +\} U ! U N \text{ or } a = , | , \}) U
variable x3 \in (\{ a | a \in M | , \}) U
track variable t;
class H = (\{ a | a \in H | , \}) U
```
procedure rewind;

<Positions tape scan just right of '♀'.>

begin [ ♀ => R ; => L, repeat ] end rewind;

procedure wind;

<Positions tape scan just left of '♀' end-mark.>

begin [ ♀ => L ; => R, repeat ] end wind;

procedure clear(track);

<Fills track with blanks.>

begin

wind, [ ♀ => ; => track,_,R, repeat ]

end clear;

procedure endtape;

<If entered scanning '♀', writes a six-track blank, otherwise fails.>
Recall that '♀' is the natural tape blank to see this adds one all-
blank square at the right end of information if the '♀' scanned is
the right end-mark. [Resp. always fails.]>

begin [ ♀ => (_,_,_,_,_,_) ] end endtape;

{procedure check_x;

<Fails unless the string x is on track 1, just right of the scan
point, in which case tape contents are unchanged.>

\text{end apply1;}
\end{align*}

(main line of program (See lemmata 2 and 3.))

\[ P0: \text{check}, [ \Rightarrow P1: \text{test, P2: } \{ \text{load} \_ r | r \in R | \text{or} \}, P3: \text{generate, P4: apply1,}
\]
\[ P5: \text{repeat } ]

end
properties of the program schema

It remains to be argued that, for given \( \forall [c] \forall [g] \ G = (M, N, R_g, B, R, s) \), the \( \Sigma \) (resp. \( \Gamma \)) \( A \) corresponding to \( G \) specified by the program schema of the preceding section has the property (\( h \)). It is not the intent of the present paper to give a rigorous proof of this fact, or even to develop the machinery to do so. The proofs of the propositions of the present section depend on the accuracy and completeness of the descriptions given as commentary in the program schema.

Two remarks are in order concerning the commentary given in the program schema: First, each assertion like

(6) 'This procedure affects the tape in manner \( F \),'

may, in view of its role in a formal proof, be considered as an abbreviation for one like

(7) 'If the state part of an instantaneous description \( I_1 \) of \( A \) corresponds to the initial position of an instance of this procedure, and the state part of an instantaneous description \( I_2 \) of \( A \) corresponds to the final position of the same instance of this procedure, and the state parts of \( I_1, I_2 \) do not differ otherwise, then there is a sequence of computational steps of \( A \) leading from \( I_1 \) to \( I_2 \) if and only if the tape part of \( I_2 \) can be derived from the tape part of \( I_1 \) in manner \( F \),'

and similarly for comments describing jumps, acceptance, rejection, and
the assignment of values to variables. Second, except possibly in the case where a lemma is provided here, the reader should not find it difficult to convince himself of the truth of the assertions so abbreviated, since the programming techniques used are not complicated.

In accordance with the general intent of the present paper and, in particular, with the fact that the translation (6) → (7) is not formally specified, the language of the present section will have formality between that of (6) and that of (7). Instantaneous descriptions will be (partially) specified as:

\[(6) \quad L(C) ,\]

where 'L' is a label occurring in the program schema and C is a condition on tape contents and values of variables. Each occurrence of the notation (6) in an assertion may be taken to abbreviate some complete instantaneous description whose state satisfies the condition C and corresponds to the label 'L', and whose tape contents satisfy the condition C. The existence of a sequence of computational steps of A leading from one instantaneous description, \(L_1(C_1)\) to another, \(L_2(C_2)\) is asserted thus:

\[L_1(C_1) \vdash L_2(C_2) .\]

In the remainder of the present section, let \(G = (H, \Pi, R, H^*, B, R, s)\) be a fixed [cs] Wk satisfying (5). Lemmata 2, 3, and 4 refer to the tm [resp. lba] A corresponding to G specified by the program schema of the preceding section.
Lemma 2: For \( U \in M \), let \( G_U = (M, N, R_M, U) \). In the procedure metagen, \( M_O((x3) = U) \vdash M_S(T,h = x) \) if and only if \( x \in L(G_U) \) [and \( |x| \leq |X| \), where \( X \) is the input to \( A \)].

Proof: The conditional statement at \( M_I \) assures that if \( M_I(T,h = x) \vdash M_S \), then \( x \in N^* \). Conversely, the same conditional statement permits \( M_I(T,h = x) \vdash M_S \). In each case, the passage \( M_I \vdash M_S \) entails no change in tape contents. Accordingly, it suffices to show \( M_O((x3) = U) \vdash M_I(T,h = x) \) if and only if \( U \overset{*}{\unrhd} x \) [and \( |x| \leq |X| \)].

\( (U \overset{*}{\unrhd} x \) [and \( |x| \leq |X| \)] \implies M_O((x3) = U) \vdash M_I(T,h = x) \): By induction on the length of a derivation \( U \overset{*}{\unrhd} x \): If length is 0, then \( x = U \). Clearly, \( M_O((x3) = U) \vdash M_I(T,h = U) \) [and \( |U| = 1 \leq |X| \)] unless \( X = \varnothing \), in which case \( (U \overset{*}{\unrhd} x \) and \( |x| \leq |X| \) is impossible by the assumption that \( G \) satisfies (5).] If length is > 0, then \( \exists_{y \in (M,N)^*} U \overset{*}{\unrhd} y \) and \( y \vdash x \) via some \( (f \rightarrow \varnothing) \in R_M \). By inductive hypothesis \( (|y| \leq |x| \leq |X|) \), \( M_O((x3) = U) \vdash M_I(T,h = y) \). Always \( M_I \vdash M_I \) with no change in tape contents, so \( M_I(T,h = y) \vdash M_I(T,h = y) \).

\[ |f| \leq |\varnothing| \leq |x| \leq |X| \), so \( M_I(T,h = y) \vdash M_I(T,h = y) \) and \( T_S = f \) via netaload \( (x \rightarrow y) \). Finally, \( M_I(T,h = y) \vdash M_I(T,h = y) \) and \( T_S = f \) via a suitable shift during application of apply2.

\( (M_O((x3) = U) \vdash M_I(T,h = x) \implies U \overset{*}{\unrhd} x \) [and \( |x| \leq |X| \) \): By induction on the smallest number of occurrences of \( M_I() \) states in a computational sequence \( M_O((x3) = U) \vdash M_I(T,h = x) \): If smallest number of occurrences is 0, then \( x = U \). If smallest number of occurrences is
> 0 , then $\exists_{\forall \in (M^*)}^{M^x(x) = U} \models M_1(T \cdot l = x) \models M_1(T \cdot l = y) \models M_1(T \cdot l = x)$ with exactly one occurrence of an $M_1(\cdot)$ state. By inductive hypothesis, $U \models_x y$. The necessary passage $M_3 \models M_1$ assures that an applicable rule was selected at $M_2$ , so $y \models y \models x$. [In any case, arrival at $M_1(T \cdot l = x)$ insures $|x| \leq |U|$.].

**Lemma 3:** In the main line of the program, if $Z \in (N^*)^*$, then

$\mathbb{P}(T \cdot l = x) \models \mathbb{P}(T \cdot l = c(Z))$ if and only if $\exists_{\forall \in (N^*)^*} x = c(x)$ and $Z \models x > x$.

**Proof:** ( $(\exists_{\forall \in (N^*)^*} x = c(x)$ and $Z \models_x x ) \models \mathbb{P}(T \cdot l = x) \models \mathbb{P}(T \cdot l = c(Z))$ ). By induction on the length of a derivation $Z \models_x x$:

If length is 0 , then $x = Z$, $x = c(Z)$. If length is > 0 , then

$\exists_{\forall \in (N^*)^*} Z \models_y Y$ and $Y \models_x x$ via some strict rule $(Y_1 \rightarrow X_1)$ derived from some $(Y_2 \rightarrow X_2) \in R$. [Because $G$ satisfies $(S)$, $|c(Y_2)| \leq |c(Y_1)|$ and $|c(X_2)| \leq |c(X_1)|$. Because $G$ is cs, $|c(Y_1)| \leq |c(Y_1)|$. Hence, by definition of $\models_x$, $|c(Y_1)| \leq |c(Y)|$, $|c(X_1)| \leq |c(X)|$, and $|c(Y)| \leq |c(X)|$. Therefore space permits representation of all of $Y$, $Y_1$, $Y_2$, $X_1$, $X_2$.] Now $\mathbb{P}(T \cdot l = x) \models \mathbb{P}(T \cdot l = x) \models \mathbb{P}(T \cdot l = x)$ and $T_3 = c(Y_2)$ $\models \mathbb{P}(T \cdot l = x)$ and $T_2 = c(X_2)$ and $T_3 = c(Y_1)$ $\models \mathbb{P}(T \cdot l = c(Y))$ by stated properties of procedures (with appropriate choices). By inductive hypothesis, $\mathbb{P}(T \cdot l = c(Y)) \models \mathbb{P}(T \cdot l = c(Z))$.

$\mathbb{P}(T \cdot l = x) \models \mathbb{P}(T \cdot l = c(Z)) \models \mathbb{P}(T \cdot l = c(X)) \models \mathbb{P}(T \cdot l = x)$ by induction on the smallest number of occurrences of $P^x(\cdot)$ states in a computational sequence $\mathbb{P}(T \cdot l = x) \models \mathbb{P}(T \cdot l = c(Z))$. If smallest number of occurrences is 0 , then $x = c(Z)$. If smallest number is
